Cloth-fold'ing Ma-chine. One in which wide goods are folded lengthwise, ironed and pressed ready for baling. In the example the cloth is passed over the bulging, spreading roller $a$, which is adjustable, and between the folders, which consist of a plate bent into a sinuous form like a flattened S. From the folders the cloth passes beneath the inclined steam-heated ironer $D$, and from that to the rollers $F'F'$, by which it is drawn forward.
