Lazy evaluation

Haskell evaluates expressions using a technique called lazy evaluation:
1. No expression is evaluated until its value is needed.
2. No shared expression is evaluated more than once; if the expression is ever evaluated then the result is shared between all those places in which it is used.

Lazy functions are also called non-strict and evaluate their arguments lazily or by need.
C functions and Java methods are strict and evaluate their arguments eagerly.

Don’t Evaluate Until Necessary

The first of these ideas is illustrated by the following function:

```haskell
ignoreArgument x = "I didn’t evaluate x"
```

Since the result of the function `ignoreArgument` doesn’t depend on the value of its argument `x`, that argument will not be evaluated:

```
$ hugs +s
> ignoreArgument (1/0)
I didn’t evaluate x
(246 reductions, 351 cells)
```

Don’t Evaluate Until Necessary...

The function `seq` forces strict evaluation when that is necessary:

```
> seq ignoreArgument (1/0)
Inf
(32 reductions, 78 cells)
```
The second basic idea behind lazy evaluation is that no shared expression should be evaluated more than once.

For example, the following two expressions can be used to calculate $3 \times 3 \times 3 \times 3$:

```
> square*square where square = 3*3
81
(30 reductions, 67 cells)
> (3*3)*(3*3)
81
(34 reductions, 45 cells)
```

Notice that the first expression requires fewer reductions than the second.

A **reduction** is the basic step of evaluating a Haskell expression, by applying a function to its argument.

Consider these sequences of reductions:

```
square * square where square = 3 * 3
-- calculate the value of square by
-- reducing 3*3 ==> 9 and replace each
-- occurrence of square with this result
==> 9 * 9
==> 81

(3 * 3) * (3 * 3) -- evaluate first (3*3)
==> 9 * (3 * 3) -- evaluate second (3*3)
==> 9 * 9
==> 81
```

Lazy evaluation means that only the minimum amount of calculation is used to determine the result of an expression.

Consider the task of finding the smallest element of a list of integers.

```
> minimum [100,99..1]
1
(2355 reductions, 3211 cells)
```

[100,99..1] denotes the list of integers from 1 to 100 arranged in decreasing order.

Instead, we could first sort and then take the head of the result:

```
> :load List
> sort [100,99..1]
[1, 2, 3, 4, 5, 6, 7, 8, ..., 99, 100]
(3430 reductions, 8234 cells)
```
Taking the Minimum...

- However, thanks to lazy evaluation, calculating just the first element of the sorted list actually requires less work in this particular case than the first solution using `minimum`:
  
  ```haskell
  > head (sort [100,99..1])
  1
  (1877 reductions, 3993 cells)
  
  > minimum [100,99..1]
  1
  (2355 reductions, 3211 cells)
  ```

Infinite data structures

- Lazy evaluation makes it possible for functions in Haskell to manipulate 'infinite' data structures.
- The advantage of lazy evaluation is that it allows us to construct infinite objects piece by piece as necessary.
- The function `ones` below generates an infinite list of 1s:
  ```haskell
  ones = 1 : ones
  
  > take 10 ones
  [1,1,1,1,1,1,1,1,1,1]
  (277 reductions, 389 cells)
  ```

Infinite data structures...

- Consider the following function which can be used to produce infinite lists of integer values:
  ```haskell
  countFrom n = n : countFrom (n+1)
  
  > countFrom 1
  [1, 2, 3, 4, 5, 6, 7, 8, ⋮Interrupted!]
  ```

Infinite data structures...  

- For practical applications, we are usually only interested in using a finite portion of an infinite data structure.
- We can find the sum of the integers 1 to 10:
  ```haskell
  > sum (take 10 (countFrom 1))
  55
  (278 reductions, 440 cells)
  ```
- `take n xs` evaluates to a list containing the first `n` elements of the list `xs`. 
Infinite data structures enable us to describe an object without being tied to one particular application of that object. The following definitions for infinite list of powers of two [1, 2, 4, 8, ...]:

```haskell
powersOfTwo = 1 : map double powersOfTwo
  where double n = 2*n
```

```haskell
> take 10 powersOfTwo
[1,2,4,8,16,32,64,128,256,512]
```

- `xs!!n` evaluates to the $n$:th element of the list `xs`.
- We can define a function to find the $n$th power of 2 for any given integer $n$:

```haskell
powersOfTwo = 1 : map (*2) powersOfTwo
twoToThe n = powersOfTwo !! n
> twoToThe 5
32
```

Fibonacci

Here’s a definition of a function that generates an infinite list of all the fibonacci numbers:

```haskell
fib = 1:1: [a+b | (a,b) <- zip fib (tail fib)]
> take 10 fib
[1,1,2,3,5,8,13,21,34,55]
```
