Object-Oriented Languages...

- 3. Polymorphism, which is the ability of a variable to store values of different types. OO languages support a special kind of polymorphism, called inclusion polymorphism, that restricts the values that can be stored in a variable of type $T$ to values of type $T$ or subtypes of $T$.

- 4. Data encapsulation. Data (instance variables) and operations (methods) are defined together.

- 5. Templates and objects. A template (class or prototype) describes how to create new objects (instances of abstract data types).

Compiling OO Languages

- Runtime type checking (a variable of type `ref T` may only reference objects of type $T$ or $T$’s subtypes).

- Because of the polymorphic nature of OO languages, we can’t always know (at compile-time) the type of the object that a given variable will refer to at run-time. When we invoke a method we can’t actually know which piece of code we should execute. Finding the right piece of code is called method lookup. It can be done by name (Objective-C) or number (C++).

- Most OO languages rely on dynamic allocation. Garbage collection is a necessary part of the runtime system of a compiler for an OO language (C++ non-withstanding). This requires runtime type description.

Object-Oriented Languages

- Object-oriented languages extend imperative languages with:
  1. A classification scheme that allows us to specify is-a as well as has-a relationships. Has-a is supported by Pascal, where we can declare that one data item has another item (a record variable has-a record field). Object-Pascal, Oberon, etc, extends this capability with inheritance which allows us to state that one data item is (an extension of) another item.

  2. Late binding, which allows us to select between different implementations of the same abstract data type at run-time.
// Example in Java

class Shape {
    double x, y;
    void draw(); { ... }
    void move(double X, double Y); {x = x+X; }
}
class Square extends Shape {
    double side;
    void draw(); { ... }
}
class Circle extends Shape {
    double radius;
    void draw(); { ... }
    double area(); { ... }
}
Example in Oberon-2

TYPE Shape = RECORD x, y : REAL END;
  Square = RECORD (Shape) side : REAL END;
  Circle = RECORD (Shape) radius : REAL END;
PROCEDURE (Self : Shape) Move (X, Y : REAL) =
BEGIN ... END Move;
PROCEDURE (Self : Shape) DefaultDraw () =
BEGIN ... END DefaultDraw;
PROCEDURE (Self : Square) SquareDraw () =
BEGIN ... END SquareDraw;
PROCEDURE (Self : Circle) CircleDraw () =
BEGIN ... END CircleDraw;
PROCEDURE (Self : Circle) ComputeArea () : REAL =
BEGIN ... END ComputeArea;

Record Layout

- Single inheritance is implemented by concatenation, i.e. the instance variables of class C are
  1. the variables of C's supertype, followed by
  2. the variables that C declares itself.
An OO language compiler would translate the declarations in the previous slide into something similar to this:

```
TYPE Shape = POINTER TO RECORD
  x, y: REAL;
END;
TYPE Square = POINTER TO RECORD
  x, y: REAL;
  side: REAL;
END;
TYPE Circle = POINTER TO RECORD
  x, y: REAL;
  radius: REAL;
END;
VAR S: Shape; Q: Square; C: Circle;
```

---

Class Templates

To support late binding, runtime type checking, etc, each class is represented by a template at runtime. Each template has pointers to the class’s methods and supertype.

```
Each method is a procedures with an extra argument (SELF), a pointer to the object through which the method was invoked.

TYPE Shape = CLASS
  x, y : REAL;
  METHOD draw(); BEGIN ···;
  METHOD move(X, Y : REAL);
    BEGIN x := x+X; · · END;
END;
```

```
PROCEDURE Shape$move (SELF : Shape; X,Y : REAL);
BEGIN
  SELF^.x := SELF^.x + X;
  SELF^.y := SELF^.y + X;
END;
```

---

- Square’s x, y fields are inherited from Shape. Their offsets are the same as in Shape.

```
TYPE $TemplateT = POINTER TO RECORD
  parent : $TemplateT;
  move : ADDRESS;
  draw : ADDRESS;
END;
TYPE Square = POINTER TO RECORD
  $template : $TemplateT;
  x, y : REAL;
  side : REAL;
END;
CONST Square$Template:$TemplateT =
  [ parent= ADDR(Shape$Template);
    move = ADDR(Shape$move);
    draw = ADDR(Square$draw); ];
```
Inclusion Polymorphism

Consider the last two lines of the example in the following slide:

- In \( L_1 \), \( S \) points to a \texttt{Shape} object, but it could just as well have pointed to an object of any one of \texttt{Shape}'s subtypes, \texttt{Square} and \texttt{Circle}.

- If, for example, \( S \) had been a \texttt{Circle}, the assignment \( \texttt{C := S} \) would have been perfectly OK. In \( L_2 \), however, \( S \) is a \texttt{Shape} and the assignment \( \texttt{C := S} \) is illegal (a \texttt{Shape} isn't a \texttt{Circle}).

```plaintext
VAR S : Shape; Q : Square; C : Circle;
BEGIN
Q := NEW (Square);
C := NEW (Circle);
S := Q; (* OK *)
S := C; (* OK *)
Q := C; (* Compile-time Error *)
L_1: S := NEW (Shape);
L_2: C := S; (* Run-time Error *)
END;
```

Method Invocation

- Sending the message \texttt{draw} to \( Q \):
  1. Get \( Q \)'s template, \( T \).
  2. Get \texttt{draw}'s address at offset 4 in \( T \).
  3. Jump to \texttt{draw}'s address, with \( Q \) as the first argument.

```plaintext
VAR Q : Square;
BEGIN
Q := NEW (Square);
Q.x := 1; Q.y := 3; Q.side := 15;
Q.draw(); Q.move(20, 30);
END;
```
Run-time Type Checking...

- The Modula-3 runtime-system has three functions that are used to implement typetests, casts, and the TYPECASE statement.
- `NARROW` takes a template and an object as parameter. It checks that the type of the object is a subtype of the type of the template. If it is not, a run-time error message is generated. Otherwise, `NARROW` returns the object itself.

1. `ISTYPE(S,T : Template) : BOOLEAN;`
2. `NARROW(Object, Template) : Object;`
3. `TYPECODE(Object) : CARDINAL;`

Run-time Checks

- Casts are turned into calls to `NARROW`, when necessary:

```pascal
VAR S : Shape; VAR C : Circle;
BEGIN
  S := NEW (Shape); C := S;
END;

VAR S : Shape; VAR C : Circle;
BEGIN
  S := malloc (SIZE(Shape));
  C := NARROW(S, Circle$Template);
END;
```

Typechecking Rules

```pascal
TYPE
  T = CLASS · · · END;  
  U = T CLASS · · · END;  
  S = T CLASS · · · END;  
VAR
  t, r : T; u : U; s : S;
```

- A variable of type T may refer to an object of T or one of T's subtypes.

<table>
<thead>
<tr>
<th>Assignment</th>
<th>Compile-time</th>
<th>Run-Time</th>
</tr>
</thead>
<tbody>
<tr>
<td>t := r;</td>
<td>Legal</td>
<td>Legal</td>
</tr>
<tr>
<td>t := u;</td>
<td>Legal</td>
<td>Legal</td>
</tr>
<tr>
<td>u := t;</td>
<td>Legal</td>
<td>Check</td>
</tr>
<tr>
<td>s := u;</td>
<td>Illegal</td>
<td></td>
</tr>
</tbody>
</table>

Run-time Type Checking

Modula-3 Type-test Primitives:

- `ISTYPE(object, T)` Is object's type a subtype of T?
- `NARROW(object, T)` If object's type is not a subtype of T, then issue a run-time type error. Otherwise return object, typecast to T.
- `TYPECASE Expr OF` Perform different actions depending on the runtime type of Expr.

- The assignment `s := t` is compiled into `s := NARROW(t, TYPE(s));`
Implementing ISTYPE

- We follow the object’s template pointer, and immediately (through the templates’ parent pointers) gain access to it’s place in the inheritance hierarchy.

```
PROCEDURE ISTYPE (S, T : TemplatePtr) : BOOLEAN;
BEGIN
  LOOP
    IF S = T THEN RETURN TRUE; ENDIF;
    S := S^.parent;
    IF S = ROOT THEN RETURN FALSE; ENDIF;
  ENDLOOP
END ISTYPE;
```

Implementing NARROW

- NARROW uses ISTYPE to check if S is a subtype of T. Of so, S is returned. If not, an exception is thrown.

```
PROCEDURE NARROW(T:TemplatePtr; S:Object):Object;
BEGIN
  IF ISTYPE(S^.$template, T) THEN
    RETURN S (* OK *);
  ELSE WRITE "Type error"; HALT;
  ENDIF;
END NARROW;
```
Exam Problem

- In the following object-oriented program
  - "TYPE U = T CLASS" means that U inherits from T.
  - NEW T means that a new object of type T is created.
  - All methods are virtual, i.e. a method in a subclass overrides a method with the same name in a superclass.

PROGRAM X;
TYPE T = CLASS [  
v : INTEGER; c : CHAR;
METHOD P(x:INTEGER); BEGIN ... END P;
METHOD Q(x:CHAR); BEGIN ... END Q;
];

TYPE U = T CLASS [  
x : REAL; k : INTEGER;
METHOD R(x:INTEGER); BEGIN ... END R;
METHOD Q(x:REAL); BEGIN ... END Q;
];
VAR t : T; u : U;
BEGIN
  t := NEW T; u := NEW U; ◊
END

1. Draw a figure that describes the state of the program at point ◊. It should have one element for each item stored in memory (i.e. global/heap variables, templates, method object code, etc.) and should explicitly describe what each pointer points to.

Organizing the Symbol Table

- In C.M’s method body we can refer to
  1. M’s locals and formals, and M’s SELF.
  2. C’s methods and instance variables.
  3. Methods and instance variables of C’s superclasses.

TYPE T = CLASS [
  v : INTEGER; c : CHAR;
METHOD P(x:INTEGER); BEGIN ... v ... c ... END;
METHOD Q(x:CHAR); BEGIN ... v ... c ... END;
];
TYPE U = T CLASS [
  c : REAL; k : INTEGER;
METHOD P(x:INTEGER); BEGIN ... v ... c ... k ... END;
METHOD Q(x:REAL); BEGIN ... v ... c ... k ... END;
];
Summary...

- A template for class \( C \) consists of (in order):
  1. A pointer to the template of \( C \)’s parent.
  2. The method addresses of \( C \)’s ancestors.
  3. Addresses of \( C \)’s methods.
  4. Other information needed by the runtime system, such as
     - The size of a \( C \) instance.
     - \( C \)’s pre- and postorder numbers, if the \( O(1) \) subtype test algorithm is used.
     - \( C \)’s type code.
     - A type description of \( C \)’s instance variables. Needed by the garbage collector.

Confused Student Email

What happens when both a class and its subclass have an instance variable with the same name?

- The subclass gets both variables. You can get at both of them, directly or by casting. Here’s an example in Java:

```java
class C1 {int a;}
class C2 extends C1 {double a;}
class C {
    static public void main(String[] arg) {
        C1 x = new C1(); C2 y = new C2();
        x.a = 5; y.a = 5.5;
        ((C1)y).a = 5;
    }
}
```

Readings and References

- Read the Tiger book:
  **Object-oriented Languages** pp. 283–298
- For information on constructing layouts for multiple inheritance, see
  – William Pugh and Grant Weddell: “Two-directional record layout for multiple inheritance.”
- The time for a type test is proportional to the depth of the inheritance hierarchy. Many algorithms do type tests in constant time:
  1. Norman Cohen, “Type-Extension Type Tests can be Performed in Constant Time.”
  2. Paul F. Dietz, “Maintaining Order in a Linked List”.

Summary

- For single inheritance languages, an instance of a class \( C \) consists of (in order):
  1. A pointer to \( C \)’s template.
  2. The instance variables of \( C \)’s ancestors.
  3. \( C \)’s instance variables.
- For single inheritance languages, subtype checks can be done in \( O(1) \) time.
- Method invocation is transformed to an indirect call through the template.
- If we can determine the exact type of an object variable at compile time, then method invocations through that variable can be turned into “normal” procedure calls.
