TEXTILE-PRINTING. "Textile" (see Weaving) is a general name for all woven fabrics (Lat. texere, to weave), and the art of ornamenting such fabrics by printing on designs or patterns in colour is very ancient, probably originating in the East. It has been practised in some form, with considerable success, in China and India from time immemorial, and the Chinese, at least, are known to have made use of engraved wood-blocks many centuries before any kind of printing was known in Europe. That the early Egyptians, too, were acquainted with the art is proved not merely by the writings of Pliny but by the discovery, in the Pyramids and other Egyptian tombs, of fragments of cloth which were undoubtedly decorated by some method of printing.

The Incas of Peru, Chile and Mexico also practised textile-printing previous to the Spanish Invasion in 1530; but, owing to the imperfect character of their records before that date, it is impossible to say whether they discovered the art for themselves, or, in some way, learnt its principles from the Asians.

There is no doubt that India was the source from which, by two different channels, Europeans derived their knowledge of block-printing. By land its practice spread slowly westward through Persia, Asia Minor and the Levant, until it was taken up in Europe—during the latter half of the 17th century. Almost at the same time the French brought it directly by sea, from their colonies on the east coast of India, samples of Indian blue and white "resist" prints, and along with them, particulars of the processes by which they had been produced.

I. Technology

Textile-printing was introduced into England in 1676 by a French refugee who opened works, in that year, on the banks of the Thames near Richmond. Curiously enough this is the first print-works on record; but the nationality and political status of its founder are sufficient to prove that printing was previously carried on in France. In Germany, too, textile-printing was in all probability well established before it spread to England, for, towards the end of the 17th century, the district of Augsburg was celebrated for its printed linens—a reputation not likely to have been built up had the industry been introduced later than 1676.

On the continent of Europe the commercial importance of calico-printing seems to have been almost immediately recognized, and in consequence it spread and developed there much more rapidly than in England, where it was neglected and practically at a standstill for nearly ninety years after its introduction. During the last two decades of the 17th century and the earlier ones of the 18th new works were started in France, Germany, Switzerland and Austria; but it was only in 1738 that calico-printing was first practised in Scotland, and not until twenty-six years later that Messrs Clayton of Bamber Bridge, near Preston, established in 1764 the first print-works in Lancashire, and thus laid the foundation of what has since become one of the most important industries of the county and indeed of the country. At the present time calico-printing is carried on extensively in every quarter of the globe, and it is pretty safe to say that there is scarcely a civilized country in either hemisphere where a print-works does not exist.

From an artistic point of view most of the pioneer work in calico-printing was done by the French; and so rapid was their advance in this branch of the business that they soon came to be acknowledged as its leading exponents. Their styles of design and schemes of colour were closely followed—even deliberately copied—by all other European printers; and, from the early days of the industry down to the latter half of the 19th century, the productions of the French printers in Jouy, Beauvais, Rouen, Alsace-Lorraine, &c., were looked upon as representing "all that was best" in artistic calico-printing. This reputation was established by the superiority of their earlier work, which, whatever else it may have lacked, possessed in a high degree the two main qualities essential to all good
decorative work, viz., appropriateness of pattern and excellency of workmanship. If, occasionally, the earlier designers permitted themselves to indulge in somewhat bizarre fancies, they were carefully refrained from any attempt to produce those pseudo-realistic effects the undur straining after which in later times ultimately led to the degradation of not only French calico-printing design, but of that of all other European nations who followed their lead. The practice of the older craftsmen, at their best, was to treat their ornament in a way at once broad, simple and direct, thoroughly artistic and perfectly adapted to the means by which it had to be reproduced.

The result was that their designs were characterized, on the one hand, by those qualities of breadth, flatness of field, simplicity of treatment and pureness of tint so rightly prized by the artist; and, on the other, by their entire freedom from those meretricious effects of naturalistic projection and recession so dear to the modern mind and so utterly opposed to the principles of applied art.

Methods of Printing.

Broadly speaking textile-printing means the local application, to textile fabrics, of any colour in definite patterns or designs, but in properly printed goods the colour becomes part and parcel of the fibre, or, in other words, the latter is dyed so as to resist washing and friction. Textile-printing, then, may be looked upon as a form of dyeing; but, whereas in dyeing proper the whole fabric is uniformly covered with one colour, in printing one or more colours are applied to it in certain parts only, and in sharply defined patterns. In principle these two branches of textile colouring are closely allied, for the colouring matters used in each case are practically identical, but in practice the means of applying the successive objects are attained bear little or no resemblance to each other. In dyeing, for instance, it is sufficient, for the most part, to immerse the fabric in an aqueous solution of the dye-stuff, stirring it about constantly or otherwise manipulating it to prevent unevenness. In printing, however, the colour must be applied by special means—either by a wooden block, a stencil or engraved plates, or rollers—and thickened to prevent it from spreading, by capillary attraction, beyond the limits of the pattern or design. Many colours also contain, besides the colour matter and thickening, all the substances necessary for their proper fixation on the cloth when the latter is simply passed through the consequent process of steaming, and others again require to be subjected to many after-treatments before they are thoroughly developed and rendered fast to light and washing.

There are five distinct methods at present in use for producing coloured patterns on cloth:—

(1) Hand block-printing.
(2) Ferrote or block-printing by machine.
(3) Engraved plate-printing.
(4) Engraved roller-printing.
(5) Stencilling, which although not really a printing process may be classed here as one.

(1) Hand Block-Printing.—This process, though considered by some to be the most artistic, is the easiest, simplest and slowest of all methods of printing.

The blocks may be made of box, lime, holly, sycamore, plane or pear wood, the latter three being most generally employed. They vary in size considerably, but must always be between two and three inches thick, otherwise they are liable to warp—a defect which is additionally guarded against by backing the wood choice with two or more pieces of cheaper wood, such as deal or pine. The several pieces or blocks are tongued and grooved to fit each other, and are then securely glued together, under pressure, into one solid block. The grain of each alternate piece running in a different direction.

The block, being planed quite smooth and perfectly flat, next has the design drawn upon, or transferred to it. This latter is effected upon its surface, either by laid paper, black and oil, or the outlines of the masses of the design. The portions to be left in relief are then tinted, between their outlines, in ammonia or benzol, for the purpose of distinguishing them from those portions which have to be cut away. As a separate block is required for each distinct colour in the design, a separate tracing must be made of each and transferred (or "put on") as it is termed to its own special block.

Having thus received a tracing of the pattern the block is thoroughly dampened, is kept in cold water, then covered with wet cloths during the whole process of "cutting." The block-cutter commences by carving out the wood around the heavier masses first, leaving the finer and more delicate work until the end, to avoid cutting away the design on the coarser parts. When large masses of colour occur in a pattern, the corresponding parts on the block are usually cut in outline, the portions filled in between being cut out so as not only to absorb the colour better, but gives a much more even impression than it is possible to obtain with a large surface of wood. When finished, the block presents the appearance of flat relief carving, the design standing out like bas-relief.

Fine details are very difficult to cut in wood, and, even when successfully cut, wear down very rapidly or break off in printing. They are therefore almost invariably built up in strips of brass or copper, or by shaping a deep groove in the surface of the block. This method is known as "coppering," and by its means many delicate little forms, such as stars, rosettes and fine sprigs can be printed, which would otherwise be quite impossible to produce by hand or machine block-printing.

Frequently, too, the process of "coppering" is used for the purpose of making a mould, from which an entire block can be made and made more accurately and easily by cutting or engraving, in wood, the original design.

The metal strips are driven to a predetermined depth into the face of a piece of lime-wood cut across the grain, and, when the whole design is completed in this way, the block is placed, metal face downwards, and heated to a sufficient degree to soften the molten tin. This heat to the inserted portions of the strips of copper to enable them to carbonize the wood immediately in contact with them, and, at the same time, firmly to fuse portions together.

When cold a slight tap with a hammer on the back of the lime-wood block easily detaches the cake of the type-metal or alloy and along with it, of course, the strips of copper to which it is firmly fixed, forming a mass, or mould, in wood of the original design.

The casting is made in an alloy of low melting-point, and, after cooling, is filed or ground until all its projections are of the same height and perfectly smooth, after which it is screwed on to a wooden support and is ready for printing. Similar moulds are also made by burning out the lines of the pattern with a red-hot steel punch, capable of being raised or lowered at will, and which when the block is moved about by hand along the lines of the pattern.

In addition to the engraved block, a printing table and colour sieves are required. The table consists of a stout framework of wood into which is set a box of storage containing in size according to the width of cloth to be printed. Over the stone table top a thick piece of woolen printer's blanket is tightly stretched to supply the elasticity necessary to give the block every chance of making a good impression on the cloth. At one end, the table is provided with a couple of iron brackets to carry the roll of cloth to be printed and, at the other, a series of guide rollers, extending over the table, are arranged by means of the heating and drying the newly printed goods. The "colour sieve" consists of a tub (known as the swimming tub) half filled with starch paste, on the surface of which floats a frame covered at the bottom with fine cloth, to catch any piece of mackintosh or small objects the "colour sieve" proper, a frame similar to the last but covered with fine woolen cloth, is placed, and forms when in position a sort of elastic trough over the bottom of which the colour is spread evenly with a brush.

The modus operandi of printing is as follows:—The printer commences by drawing a length of cloth, from the roll, over the table, and marks it with a piece of coloured chalk and a ruler to indicate where the first impression of the block is to be applied. He then applies his block in two different directions to the colour on the sieve and finally presses it firmly and steadily on the cloth, ensuring a good impression by striking it smartly on the back with a wooden mallet. The second impression is made in the same way, the printer taking care to see that it fits exactly to the first, a point which he can make sure of by means of which the prints are provided at each corner and which are arranged in such a way that when those at the right side or at the top of the block fall upon those at the left side or the bottom of the previous impression the two prints join up exactly and continue the pattern without a break. Each succeeding impression is made in precisely the same manner until the length of cloth on the table is fully printed. When this is done it is wound over the drying rollers, then being brought forward to be cut to length.

If the pattern contains several colours the cloth is usually first printed throughout with one, then dried, re-wound and printed with the second, the same operations being repeated until all the colours are printed, or a brush. Printed in this way, the cloth is known as "double-dyed." Many modifications of block-printing have been tried from time to time, but of these only two—"tobying" and "rainbowing"—are of any practical value. The object of "tobying" is to print the several colours of a multicolour pattern at one operation, and for this purpose a block with the whole of the pattern cut upon it, and a specially constructed "colour sieve" are employed. The sieve consists of a thick block of wood, on one side of which a series...
of compartments are hollowed out, corresponding roughly in shape, size and position to the various objects cut on the block. The tops of the dividing walls of these compartments are then coated with melted pitch, and a piece of fine woolen cloth is stretched over the whole block down on the cloth so as to make it quite fitting to the top of each wall; finally a piece of string soaked in pitch is cemented over the woolen cloth along the lines of the dividing walls, and after boring a hole through the bottom of each compartment, the pressure of steel was ready for use. Each block was filled with its special colour through a pipe connecting it with a colour box situated at the side of the sieve and a little above it, so as to keep the pressure of the basin in handkerchief of the required colour, or that made up a certain colour which it transfers to the cloth in the usual way. By this method of "tobying" from two to six colours may be printed at one operation, but it is obvious that it is only applicable to patterns where the different coloured objects are placed at some little distance apart, and that, therefore, it is of but limited application.

Block-printing by hand is a slow process; it is, however, capable of yielding highly artistic results, some of which are unobtainable by any other means, and it is, therefore, still largely practised for the highest class of work in certain styles.

(2) Engraved.—The "perrotine" is a block-printing machine invented by Perrot of Rouen in 1834, and practically speaking is the only successful mechanical device ever introduced for this purpose. For some reason or other it has rarely been used in this country, in part, in part, on the Continent, and although block-printing of all sorts has been replaced to such an enormous extent by roller-printing, the "perrotine" as employed in this country was such an important machine that it was not unknown with certainty, although the principle of the method was shown to be practical by the printing of one colour with perfectly satisfactory results. The difficulty was to keep the six rollers, each carrying a portion of the pattern, correctly in position with each other. This defect was soon overcome by Adam Parkinson of Manchester, and in 1785, the year of its invention, Bell's machine with Parkinson's improvements, was employed in the manufacture of handkerchiefs at Harrogate, Hall & Co., of Bamberg, Preston, for the printing of calico in from two to six colours at a single operation.

What Parkinson's contribution to the development of the modern block-printing machine was is not known with certainty, but it was possibly the invention of the delicate adjustment known as "the box-roller," whereby the rollers can be turned, whilst the machine is in motion, either in or against the direction of their rotation.

In its simplest form the roller-printing machine consists of a strong cast iron cylinder mounted in adjustable bearings capable of sliding up and down slots in the sides of the rigid iron framework to which it is fastened. Beneath this cylinder the engraved copper roller rests in stationary bearings and is supplied with colour from a wooden roller which revolves in a colour-box below it. The copper roller is mounted on a stout steel axle, at one end of which a cog-wheel is fixed to gear with the driving wheel of the machine, and at the other end a smaller cog-wheel to drive the colour-furnishing roller. The colour is pressure cylinder is wrapped with several thicknesses of〔spatial materials〕, forming the key to the object of which is to provide the elasticity necessary to enable it to properly force the cloth to be printed into the lines of engraving. A further advantage is gained from the use of a thin sharp blade of steel which rests on the engraved roller and serves to scrape off every vestige of superfusional colour from its surface, leaving only that which rests in the engraving. On the perfect ground, the roller, which is known as "the "perrotine," and as its sharpness and angle of inclination to the copper roller varies with the styles of work in hand it requires an expert to get it up" (sharpened) properly and considerable practical experience to know exactly what qualities it should possess in any given case. In order to prevent it (the "doctor") from wearing irregularly it is given a to-and-fro motion so that it is constantly changing its position and is never in contact with any one point of the engraving for more than a moment at a time. A second "doctor" of brass or a similar alloy is frequently added on the opposite side of the roller to that occupied by the steel or "cleaning" doctor; it is known technically as the "lint doctor" from its purpose of removing loose filamentary material which the roller picks off the cloth during the printing operation. The steel or "cleaning doctor" is pressed against the roller by means of levers, but the "lint doctor" is usually just allowed to rest upon it by its own weight as its function is simply to percept the lint which becomes detached from the cloth and would, if not cleaned from the roller, mix with the colour and give rise to defective work.

The working of the machine will be best understood by referring to the accompanying diagrammatic sketch of a single colour (fig. 1).
A is the cast iron pressure cylinder; B the lapping with which it is usually wrapped; C the engraved copper printing roller; D the steel "cleaning doctor"; E the brass "lint doctor"; F the colour-furnishing roller; G the colour-trough; H the box wheel; I a roller; J the box wheel; K the steel blanket, and L the cylinder A or the cylinder D. The cylinder D is made of a material which is easily cut, such as an endless woolen blanket or thin metal with a sharp-pointed knife, and the uncut portions representing the part that is to be "reserved" or left uncoloured. The sheet is then placed in a printing machine and the cylinder D is wound down with the colour plate, and the metal is forced into frictional contact with the roller C; the machine is then set in motion, turning in the direction indicated by the arrows; the cloth is now introduced between A and C and as it leaves the machine it is covered with the material that has been situated above and heated by steam. The printing roller C is the only part of the machine directly connected with the motor or main drive of the works through the cog-wheel on its axis, the other parts being joined to it, either by friction as in the case of the cylinder or by a spur wheel as in that of the colour-furnishing roller. The mode of printing is almost self-evident; the roller C revolving in the direction of the arrow takes colour from the "furnisher" F, the excess is scraped off by the "doctor" G and, in continuing its course, it comes in contact with the cloth K, which being pressed by the cylinder A into the engraving abstracts the colour, and of course receives an exact impression of the engraved pattern.

Large printing machines from two to sixteen colours are precisely similar in principle to the machine described, but the details are naturally more complex and difficult to operate. In a twelve-colour machine, for example, twelve copper rollers, each carrying one portion of the design, are arranged round a central cylinder, or "rim," and all the rollers are moved or fixed to give the proper impression on the cloth. The setting and moving of the rollers is done by means of gears and levers. In the case of the "rim," one of them is connected by means of a rack and pinion with the driving wheel of the machine. The other mechanisms are similar to those described above, combinations of them are not infrequently employed. Sometimes a pattern is printed partly by machine and partly by hand; and sometimes a cylindrical block is used along with engraved patterners in the ordinary printing machine. The block in this latter case is in all respects, except that of shape, identical with a flat plate or "coppered" block, but, instead of being dipped in color, it is dipped in a bath of a chemical solution of a substance which makes it take in color, and the color is forced on to it, through the holes in the stencil, by mechanical means.

(6) Other Methods of Printing.—Although most work is executed through one of the nine or ten devices already described, many improvements have been made in printing machines and many additions made to their already wonderful capacities. Chief amongst these are embodied in the "Intermixer" or "Duplex" machine, which consists of two ordinary machines combined so that when the cloth passes, fully printed on one side from the first, its plain side is exposed to the rollers of the second, which print an exact duplicate of the first. It is in such a manner that the roller of the second machine A is placed so that it is the same as the roller of the first machine B. Thus it prints a second set of rollers every three yards, sometimes every nine yards—and it is to effect this, with rollers of ordinary dimensions, that "intermittent" machines are used. The body of the "intermixers" is made up of 30 yards with eight rollers; these then drop away from the cloth and others, which have up to then been out of action, immediately fall into contact and print a border or crossbar, say one yard wide, across the piece; they then recede from the cloth and the first eight again return and print another six yards, and so on continually.

The "Duplex" or "Reversible" machine derives its name from the fact that it prints both sides of the cloth. It consists really of two ordinary machines so combined that when the cloth passes, fully printed on one side from the first, its plain side is exposed to the rollers of the second, which print an exact duplicate of the first. The design is so arranged that it prints a second set of rollers every three yards, sometimes every nine yards—and it is to effect this, with rollers of ordinary dimensions, that "intermittent" machines are used. The body of the "intermixers" is made up of 30 yards with eight rollers; these then drop away from the cloth and others, which have up to then been out of action, immediately fall into contact and print a border or crossbar, say one yard wide, across the piece; they then recede from the cloth and the first eight again return and print another six yards, and so on continually.

The advantages possessed by roller-printing over all other processes are mainly three: firstly, its high productivity—10,000 to 12,000 yds. being commonly printed in one day of ten hours by a single printer; secondly, its capacity is limited only by the reproduction of every style of design, ranging from the fine delicate lines of copperplate engraving and the small "repeats" and limited colours of the "perrotine" to the broadest effects of black and white to patterns violet, 80 in.; and thirdly, the wonderful exactitude with which each portion of an entire multicolour pattern can be fitted into its proper place, the entire absence of faulty joints at the edges of the "repeat" or repetition—a consideration of the utmost importance in fine delicate work, where such a blur would utterly destroy the effect.

(5) Stencilling.—The art of stencilling is very old. It has been applied to the decoration of textile fabrics from time immemorial by the Japanese, and, of late years, has found increasing employment in Europe for certain classes of decorative work on woven goods for furnishing purposes. A sheet of stout paper or thin metal with a sharp-pointed knife, the uncut portions representing the part that is to be "reserved" or left uncoloured. The sheet is then placed in a printing machine and the colour is brushed through its interstices.

It is obvious that with suitable planning an "all over" pattern may be as easily produced by this process as by hand or machine printing; and a few years ago several patterns, as many as 500 colours as plates may be introduced into it. The peculiarity of stencilled patterns is that they have to be held together by "ties," that is to say, certain parts of them have to be left uncut, so as to connect them. The "ties," however, may be made to fall apart in separate pieces. For instance, a complete circle cannot be cut without its centre dropping out, and, consequently, its outline has to be interrupted at convenient points by "ties" or uncort portions. Similarly with other objects. The necessity for "ties" exercise great influence on the design, and in the hands of a designer of indifferent ability they may be very unsightly. On the other hand, a clever man utilizes them to supply the drawing, and when thus treated they form an integral part of the pattern and enhance its artistic value whilst complying with the conditions prevalent and the processes.

For single-colour work a stencilling machine was patented in 1894 by S. H. Sharp. It consists of an endless stencilled plate of thin sheet steel which passes continuously over a revolving cast iron cylinder B, to which the cloth A is fastened, and the colour is forced on to it, through the holes in the stencil, by mechanical means.

The printing of yarns and warp is extensively practised. It is usually done by a simple sort of "surface" printing machine and calls for no special mention.

Lithographic printing, too, has been applied to textile fabrics with somewhat qualified success. Its irregularity and the difficulty of printing "s Hill" have hitherto limited its use to the production of decorative panels, equal in size to that of the plate or stone, and complete in themselves.

Engraving of Copper Rollers

The engraving of copper rollers is one of the most important branches of textile-printing and on its perfection of execution depends, in great measure, the ultimate success of the designs. Roughly speaking, the operation of engraving is performed by three different methods, viz. (1) By hand with a graver which cuts the metal away; (2) by etching, in which the pattern is dissolved out with nitric acid; and (3) by machine, in which the pattern is simply indented.

(1) Engraving by hand is the oldest and most obvious method of engraving, but is the least used at the present time on account of the unknown length required to engrave a pattern. The employment of so much time and labour, and the difficulty of securing uniformity and accuracy, have restricted its use to the production of decorative panels, equal in size to that of the plate or stone, and complete in themselves.

The etching process is adaptable to the enlargement of design and on account of an enlarged camera and prisms or reflectors. On this plate it is then painted in colours roughly approximating to those in the original, and the outlines of the copper rollers are carefully traced to patterns. The necessity for this is that in subsequent operations the design has to be again reduced to its original size and, if the outlines on the zinc plate were too small at first, they would be impracticable either to etch or to engrave. The result is that a graver applied to a varnished copper roller are both engraved at one and the same operation in the pantograph machine. This machine is capable of reducing a pattern on the zinc plate from one-half to one-tenth
TEXTILE-PRINTING

of its size, and is so arranged that when its pointer or stylus is moved along the engraved lines of the plate to a series of round points at the end of each line through which the varnish is covered. These diamond points vary in number according to the number of times the pattern is required to repeat along the length of the roller. Each colour of a design is transferred in a separate roller. The roller is then placed in a shallow trough containing nitric acid, which acts only on those parts of it from which the varnish has been scraped. To ensure evenness of the roller more or less even portions throughout the whole time are simply "mordants" thickened. A mordant is the metallic salt or other substance which combines with the colouring principle to form an insoluble colour-lake, either directly by coating, or indirectly by building up the grains of the lake. All printing colours require to be thickened, for the twofold object of enabling them to be transferred from colour-box to cloth without loss and to prevent them from "running" or spreading beyond the limits of the design. With the exception of albumen all these are made into pastes, or dissolved, by boiling in double or "jacketed" pans, between the inner and outer casings of which either steam or water may be used. Chemical and mechanical catalysators are also fitted in these pans to mix the various ingredients together, and to prevent the formation of lumps by keeping the contents thoroughly stirred during the whole time they are being reduced or dissolved.

Thickening Agents. — The thickening agents in most general use as vehicles in printing, are starch, flour, gum aramitic, gum sepal, and gum tragacanth. Each of these has its dextrine or dextrine and albumen. With the exception of albumen all these are made into pastes, or dissolved, by boiling in double or "jacketed" pans, between the inner and outer casings of which either steam or water may be used. The principal thickening agents are starch and flour, which are either alone or combined with gum arabic and gum tragacanth.

Preparation of Cloth for Printing. - Goods intended for calico-printing ought to be exceptionally well bleached, otherwise the yellowish, mottling, and other stains and other colours used for the cloth are certain to arise during subsequent operations. Particulars of bleaching will be found in the article BLEACHING (q.v.).

The chemical preparations used for special styles will be mentioned later. To prepare for all styles and for many other purposes, the bleached cloth must be thoroughly soaked and washed, and this is done by immersing it in water and then by boiling it. Washing may be done by boiling the cloth in water for two or three hours, or by boiling the water in which the cloth has been placed for several hours. The cloth is then washed, and the washings are thrown away. The process of washing and bleaching is repeated until the cloth is perfectly clean.

Preparation of Colours. - The art of making colours for textile-printing demands both chemical knowledge and extensive technical experience, for their ingredients must not only be properly proportioned to each other, but they must be specially chosen and compounded for the particular style of work in hand. For a pattern containing only one colour any mixture whatever may be used so long as it fulfils all conditions as to shade, quality and fastness; but when two or more colours are associated in the same design each must be capable of undergoing without injury the various operations necessary for their development and fixation on the others. All printing pastes whether containing colouring matter or not are known technically as "colours," and are referred to as such in the sequence.

This is considerably in composition. The greater number of them contain all the elements necessary for the direct production and fixation of the colour-lake. Some contain the colouring matter alone and require no after-treatment for fixation; others contain only the colouring matter and need only be mixed with gum arabic, gum tragacanth, and albumen. With the exception of albumen all these are made into pastes, or dissolved, by boiling in double or "jacketed" pans, between the inner and outer casings of which either steam or water may be used. Chemical catalysators are also added in these pans to mix the various ingredients together, and to prevent the formation of lumps by keeping the contents thoroughly stirred during the whole time they are being reduced or dissolved.

Starch Paste. — This is made by mixing 15 lb of wheat starch with a little cold water to a smooth creamy paste; a little olive oil is then added and sufficient water to bring it to the right consistency. The mixture is then thickened by being boiled for about an hour and, after cooling, is ready for use.

Flour Paste is made in a similar way to starch paste. At the present time it is rarely used for anything but the thickening of aluminium and iron mordants, for which it is considered by some to be preferable to the other old thickenings, but their expense prevents them from being used for any but pale delicate tints. They are especially useful thickenings for those light grounds of soft colours and water paints which are not fast to the process of washing and bleaching, and which therefore require the beautifully clear and perfectly even tints resulting from the use of natural gums. Very dark colours cannot well be obtained with gum sepal or gum arabic thickenings: they come away too easily with washing, the latter gum being useful only in combining fully with the fibres. Stock solutions of these two gums are usually made by dissolving 6 or 8 lb of either in one gallon of water, either by boiling in the vessel or in the gas-flame. To this stock gum or dextrine prepared by boiling starch. It varies considerably in composition—sometimes being only slightly roasted and consequently only partly converted into dextrine, and at other times being highly torrefied, and almost completely soluble in cold water and very dark in colour. Its thickening power decreases and its "gummy" nature increases as the temperature at which it is roasted is raised. The lighter coloured gums or dextrines will make a good thickening with from 2 to 3 lb of gum to one gallon of water, but the darkest and most highly calcined require from 6 to 10 lb per gallon to give a substantial paste. Between these limits all qualities are obtainable. The darkest qualities are very useful for strongly acid colours, and the exception of gum sepal, are the best for strongly alkaline colours and discharges. Like the natural gums, neither light nor dark British gums penetrate into the fibres of the cloth and so are only as useful as the starch or flour pastes, and are therefore unsuitable for very dark strong colours.

Gum tragacanth, or "Dragon," is one of the most indispensable thickening agents possessed by the textile printer. It may be mixed in any proportion with starch or flour pastes, and is useful when added to starch paste it increases its penetrative power, adds to its softness without diminishing its thickness, makes it easier to wash off the fabric and conducive to much more effective printing than the paste alone. Used by itself it is suitable for printing all kinds of dark grounds on goods which are required to retain their soft clothly feel. A tragacanth mucilage may be made either by allowing it to stand for twenty-four hours in warm water and then boiling it up until it is perfectly smooth and homogeneous. If boiled under pressure it gives a very fine smooth mucilage (not a solution proper), much thinner than if made in cold.

Albumen. — Albumen is both a thickening and a fixing agent for
insoluble pigments such as chrome yellow, the ochres, vermilion and ultramarine. Albumen is always dissolved in the cold, a process which takes several days when large quantities are required. The usual strength of the solution is 4 lb per gallon of water for blood albumen and 6 lb per gallon for egg albumen. The latter is expensive and only used for the lightest shades. For most purposes one part of albumen solution is mixed with one part of tragacanth mucilage, this proportion of albumen being found amply sufficient for the fixation of all ordinary pigment colours. In special instances the blood albumen solution is made as strong as 50 per cent., but this is only in cases where very dark colours are required to be absolutely fast to washing. After printing, albumen-tanned colours are exposed to hot steam, which coagulates the albumen and effectually fixes the colours.

Formerly colours were always prepared for printing by boiling the coagulated colouring matter and solvents, together, then cooling and adding the various fixing agents. At the present time, however, concentrated solutions of the colouring matters and other adjuncts are often simply added to the cold preparations, of which large stocks are kept in stock.

Colours are reduced in shade by simply adding more starch or other paste. For example, a dark blue containing 4 oz. of methylene blue per gallon may readily be made into a pale shade by adding to it thirty times its bulk of starch paste or gum, as the case may be. Similarly with other colours.

Before printing it is very essential to strain or sieve all colours in order to remove fine grit and sand, &c., which would inevitably damage the highly polished surface of the engraved rollers and result in bad printing. Every scratch on the surface of a roller prints a fine line in the cloth, and too much care, therefore, cannot be taken to remove, as far as possible, all grit and other hard particles from every colour.

The staining is usually done by squeezing the colour through fine cotton or silk cloths. Mechanical means are also employed for colours that are used hot or are very strongly alkaline or acid.

**STYLES OF PRINTING**

The widely differing properties of the hundreds of colouring matters now on the market give rise to many different styles of textile-printing. Generally speaking, these fall into the following two great divisions—

1. Direct printing.
2. The printing of a mordant upon which the colour is afterwards dyed.
3. The discharge style.
4. The resist or reserve style.

The fact that each of these divisions is further sub-divided into many smaller divisions renders it out of the question to give more than a few typical examples of the various styles they include.

**Direct Printing**—This style is capable of application to almost every class of colour known. Its essential feature is that the colouring matter and its fixing agent are both applied to the fabric simultaneously. In some instances the fabric requires to be prepared for certain of the colours used along with those characteristic of the process; but this is one of many cases where two styles are combined, and it must be classed with the one which is most resplendent.

(a) Application of Mordant Dye-Stuffs.—Mordant colours include both artificial and natural dye-stuffs (see also DYING), the most important of all being alizarine, an artificial preparation of the colouring-principle of the madder root. With different metallic oxides alizarine forms different colour-lakes—all exceedingly fast to light and soap. Aluminium mordant gives red and pink lakes; iron mordant, purples and lavendars; chromium yields maroon; and uranium gives grey shades. Mixture of iron and aluminium produce various tones of chocolate and brown.

In addition to alizarine the following are a few of the more important dye-stuffs employed in textile-printing:

Alizarine orange with aluminium and chrome mordants for orange and warm brown shades respectively; alizarine bordeaux, with alumina, for violets; alizarine blue with chrome and zinc for dark blue shades; coeruleine and alizarine viridina for greenish and olives with chromium mordants; galloxyane, chrome violet blue, alizarine cyanine, &c., with chromium for various shades of blue, red and violet; alizarine yellows and anthracene brown for yellows and fawn shades respectively with either aluminium or chrome mordants.

The natural dye-stuffs belonging to this series are chiefly: logwood, with chromium and iron mordants; Persian blue, logwood, brazilwood, and indigo; marooning, with chromium and tannin, and indigo; madder, chromo- and persian blue, with tannin; and indigo. Alizarine blue being perhaps as good as any, and the malachite greens the least stable.

Their application is simple. A solution of the colouring matter is applied to the requisite quantity of starch paste or gum, and, when well mixed in, the tannin is added in the form of a solution also. If desired they may be boiled up like the extract dye-stuffs (logwood, &c.), but this is not necessary unless large quantities are required, when it would be more convenient to boil the whole at once than to mix small batches by hand.

Alizarine reds and pinks are the most complicated of the mordant colours, requiring for their proper production the addition of brightening agents, such as oxalate of tin, oils, tartaric acid, and also acetate of lime. This also applies to alizarine orange, but all the other colours are very simple to compound and are stable for a long time after making. Red, pinks and oranges are best prepared freshly each day; their constituents are liable to combine if the colour stands twenty-four hours before printing.

The following types of recipes will give some idea of the way in which colours are mixed—

**Red.**

61 gallons thick starch and tragacanth paste.
1 lb alizarine (20 per cent. commercial paste).
1 lb nitrate of alumina, 18° Tw.
1 lb acetate of lime, 28° Tw.
1 lb oxalate of tin, 10° Tw.
1 1/10 lb oxalate of lime, 10° Tw.
11/2 lb oxalate of tin.
11/2 lb citrate of alumina, 40° Tw.

For reds and pinks the nitrate, sulphocyanide and citrate of alumina are generally preferred in practice to the acetate though the latter is also largely used. Oranges from alizarine orange are made similarly.

**Purple.**

2 gallons starch paste.
1 lb blue shade alizarine, 20 per cent.
1/3 lb acetic acid.
1/2 lb nitrate of alumina, 18° Tw.
1 lb acetate of lime, 28° Tw.
1 lb acetate of iron, 24° Tw.

**Maroon.**

3/4 gallons starch paste.
1 lb alizarine, 20 per cent.
1/2 lb acetate of chrome, 32° Tw.
1/2 lb acetate of lime, 28° Tw.

**Blues and the other colours are made by leaving out the lime in the last recipe and replacing the alizarine with another colour.**

**Alizarine Blue.**

1 lb alizarine blue shade (powd.).

(Light Shade.)

1 gallon water,
3 1/3 lb thick paste.
1/2 lb acetate of chrome, 40° Tw.

**Logwood and other natural colours are specially boiled.**

**Logwood Black.**

15 lb starch.
10 lb British gum.
4 gallons water.
1 lb acetic acid.
1 lb logwood extract, 48° Tw.
1 lb querctin extract, 45° Tw.

Boil, cool and add—
1 lb red prussiate of potash.
1 gallon water.
2 lb acetate of chrome, 40° Tw.
2 oz. chlorate of potash.

**Quercetin Yellow.**

1 gallon querctin extract, 45° Tw.
6 lb water.
1 lb starch.

Boil, cool and add—
1/2 gallon acetate of chrome, 30° Tw.

The proportions here given are liable to variations according to circumstances. Indeed, no two works employ quite the same recipes, although the proportion of mordant to dye-stuff is pretty generally known and observed.

To print after dyeing, the goods are dried, steamed for one hour, and then washed and finished.

(b) Application of Basic Aniline Dye-Stuffs.—These colours all form insoluble lakes with acid; hence tannic acid is the common fixing agent of the group. Arsenic in combination with alumina also gives basic-colour lakes, but their poisonous character and their inferior fastness to most reagents considerably limit their application.

The more important basic dye-stuffs are: methylene blue, methyl violet, rhodamine, auramine yellow, safranine emerald green and indoline blue. Most of them are fairly fast to soaping, but towards the action of light or Persan blue they vary a good deal. Methylene blue being perhaps as good as any, and the malachite greens the least stable.

Their application is simple. A solution of the colouring matter is applied to the requisite quantity of starch paste or gum, and, when well mixed in, the tannin is added in the form of a solution also. If desired they may be boiled up like the extract dye-stuffs (logwood, &c.), but this is not necessary unless large quantities are required, when it would be more convenient to boil the whole at once than to mix small batches by hand.
Methylene blue will serve as a type of the method by which all basic colours are compounded.

Blue: 2 gallons methylene blue, 10 per cent. solution in water and acetic acid.

6 " thick starch paste.

1 " tragancanth mucilage.

1 " tannic acid solution, 50 per cent.

10 gallons.

All other basic colours are made up for printing in a similar way by replacing the blue with the required dye-stuff. After printing, goods containing basic dyes are " steamed," and passed through a solution of tartar emetic, or other salt of antimony, whereby an insoluble double tannate of antimony and colouring matter is produced, which constitutes a much faster colour than the single tannate of the dye-stuff.

Basic colours may be printed along with " mordant " and albumen for greater lightness.

(c) Application of Direct Dyeing Colours.—These colours have a natural affinity for the cotton fibre and therefore require no mordant. They are not very fast, however, and, though used enormously in the dyeing of plain shades, they find but little employment in printing except for the tinting of printed goods, and for the " crepe " style, where the colours must be able to withstand the action of caustic soda.

The following table gives the composition of the colours in use. In very light shades with the addition of a slightly alkaline salt (phosphate of soda) and sulphate of soda. Amongst the hundreds of direct colours equally suitable for printing mention may be made of the idea for printing. Diamine sky-blue for blues, diamine violet, and diamine, chrysanth, chloramine and dahl yellows. In fact, most of the benzidine, diamine, dianil and Congo dye-stuffs can be used for printing, but with the exception of the former none of them with the exception of the light yellow and washing to anything like the extent that " mordant " and basic colours will. The general formula for printing these colours is as follows:

\[
\frac{4}{g} \text{oz.} \text{ colouring} \quad \text{water.}
\]

\[
\frac{1}{2} \text{g.} \text{ starch or tragancanth thickening.}
\]

\[
2 \text{oz.} \text{ phosphate of soda.}
\]

\[
2 \text{oz.} \text{ sulphate of soda.}
\]

After printing, with direct colours, the goods are first steamed, then slightly washed in a weak tepid soap solution and finally finished.

(d) Application of Pigment Colours.—Before the introduction of coal-tar colours, pigments and lakes played a much more important part in textile-printing than they do at present, though they are still largely used for certain styles of work. They form a series of colours more difficult to work than those already mentioned, but very fast to soap and light.

Pigment colours, being insoluble mineral precipitates or lakes, can only be fixed on the fibre mechanically; consequently they require to be applied in conjunction with vehicles which cause them to adhere to the fabric in much the same way that paint adheres to wood.

Of these vehicles, albumen is the most important and the best. It forms a smooth viscous solution with cold water, and mixes readily with all the colours used in pigment printing, and possesses the property of coagulating when heated to the temperature of boiling water. When cloth printed with colours containing albumen is passed through a calender, as in the indigo discharge style, the albumen coagulates, forming a tough insoluble colloidal deposit, which firmly fixes on the fibre any colour with which it is mixed.

The chief colours employed in pigment printing are: chrome yellow and orange, Guignet's green or chrome green; artificial ultramarine; lamp black for greys; the various ochres for golds and bronzes; zinc oxide; vermillion and its substitutes, and occasionally lakes of the natural and artificial colouring matters. All these bodies are employed in exactly the same way and may be mixed together in any proportion to form compound shades. The amount of albumen necessary to fix them varies according to the depth of shade required (between 10 and 25 per cent. of the total weight of the made-up printing colour), and although it is usually considered in text-books as a thickening agent it is rarely used as such in practice, and its chief value lies in the amount of its thickening effect. As a rule the colouring matter is beaten up into a smooth paste with the necessary quantity of a strong solution of albumen and then reduced to its proper strength by the addition of tragancanth mucilage or starch paste.

The main factor in the successful working of pigment colours is their fineness of division; the finer they are the better they print and the more beautiful is their quality of colour. If they are too coarse to rise to innumerable defects, either by sticking in the engraving or by scratching the roller, or, if they print at all, by yielding uneven masses of colour, granular and speckled in appearance and quite unsaleable. Even when finally ground they are liable to clog the engraving of the roller, defect which is more or less successfully overcome by replacing the colour-furnishing roller in the printing machine by a revolving brush.

The following formula of dark ultramarine blue will serve as a type of all other pigment printing colours:

- 24 lb artificial ultramarine.

Place in grinding machine and beat up gradually with

- 4 gallons 40 per cent. blood albumen solution.

- 2 gallons tragancanth mucilage, 8 oz. per gallon.

- ammonium.

- glycerin.

- turpentine.

- olive or cotton-seed oil.

Make to 8 gallons with tragancanth or water, and grind the whole thing until perfectly homogeneous.

The small quantities of ammonia, turpentine, glycerin and oil are added to prevent the colour from frothing during the printing process.

Chrome yellows and oranges are frequently mixed with a little calcium nitrate to counteract the action of sulphurated hydrogen on the lead salts.

The great disadvantage of pigment colours is that although extremely fast to light and soap they are liable to rub off, if the fabric is subjected to much friction in washing. They also impart considerable stiffness to the goods, and for these two reasons they are therefore restricted to the printing of small patterns, or are used for such styles as window-blinds where the stiffness is not objectionable. The use for printing the grounds or " blotches " of multicolour patterns, the small quantity of albumen they then contain being insufficient to appreciably affect the stiffness of the goods. In very rich or chintz styles too—notably indigo—they find extensive use, and on the whole they constitute a most useful class of colours.

(e) Application of Indigo.—Indigo is printed on cloth by several different methods, the chief of which are: (1) Schleiper and Baun's glycerol process; (2) the hydro sulphite process; and (3) the production of indigo on the fibre itself by means of Kalle's indigo salt and several other artificial preparations.

The first and second processes depend upon the facts that indigo in presence of caustic alkalis may be converted into indigo-white by reducing agents, and that the indigo-white, being soluble in the alkali, penetrates into the fibres of the cloth, where it is subsequently re-oxidised to its original insoluble state.

In Schleiper and Baun's process (also known as the glycerol process) the cloth is first prepared in glycerol, and then printed with a colour containing finely ground indigo, caustic soda and dextrine thickening (made with caustic soda). After printing, the cloth is "aged," that is, passed through damp steam for a few minutes to effect the reduction and solution of the indigo, and then hung up in a cold chamber for a day or two, in order to re-oxidise the indigo-white to indigo by the action of the oxygen in the air. A wash in cold water finally completes the fixation of the colour, and the cloth may then be soaped and finished as usual. The cloth is prepared by running through a box containing a 30 per cent. solution of glycerol in water; the excess is squeezed out in a mangle, and the cloth dried. It is then printed with the following colours according to the requirements:

<table>
<thead>
<tr>
<th>Colour</th>
<th>Dark</th>
<th>Medium</th>
<th>Light</th>
</tr>
</thead>
<tbody>
<tr>
<td>Blue</td>
<td>1 gal.</td>
<td>1 gal.</td>
<td>1 gal.</td>
</tr>
<tr>
<td>Blue</td>
<td>1 gal.</td>
<td>1 gal.</td>
<td>1 gal.</td>
</tr>
<tr>
<td>Blue</td>
<td>1 gal.</td>
<td>1 gal.</td>
<td>1 gal.</td>
</tr>
</tbody>
</table>

The printed goods should be dried quickly, and "aged" as soon as possible to prevent the absorption of carbonic acid gas from the air, after which the operations already mentioned may be proceeded with at leisure.

The well-known blue and red pattern is produced by this process, the only difference being that, instead of white cloth, turkey and other coarse cloths is used, the strong grey and red being dissolved out, or "discharging," completely the colour from those parts of the cloth upon which it falls, and leaving the indigo as a blue pattern on a red ground.

In the hydro sulphite process, which is much quicker than the preceding, the reducing agent, the indigo and the alkali are all printed together on unprepared white cloth. The goods are then "aged" and allowed to rest for a short time, after which they are washed-off in cold water first, until the indigo is thoroughly re-oxidised, and then in hot water or soap.

The hydro sulphite printing colour is as follows:

<table>
<thead>
<tr>
<th>Colour</th>
<th>100 parts hydro sulphite N. (or 100 of the concentrated product).</th>
</tr>
</thead>
<tbody>
<tr>
<td>Alkaline dextrine paste.</td>
<td>450 gal.</td>
</tr>
<tr>
<td>Indigo 20 per cent. paste (ground up in gum).</td>
<td>150 gal.</td>
</tr>
<tr>
<td>Alkaline dextrine paste.</td>
<td>200 gal.</td>
</tr>
</tbody>
</table>

Thickening 150 parts dextrine or British gum.

150 gal. caustic soda, 70° Tw.

Print dry, "aged" and wash off in a copious supply of cold water.
The third process with Kalle's salt is not properly speaking the printing of indigo, but of a special preparation capable of forming indigo when treated with caustic alkalies. The salt is merely dissolved and thickened with gum or starch, printed, and then passed direct through a solution of caustic soda, when the indigo is immediately developed. Instead of being passed through the alkali, which is apt to cause the colour to run before it is properly developed, the cloth is more commonly printed with thickened caustic soda, whereby the indigo is equally well produced without any fear of "running."

Besides indigo, other vat dye-stuffs, such as indanthrones, the algin, helianthus and chia colours, thionindigo scarlet, &c., are also printed largely at the present time, yielding colours of hitherto unattained fastness to washing and to light.

(f) Insoluble Azo- Colours.—These colours do not exist as such, but require to be produced on the fibre itself from their components. They form a range of exceedingly fast colours, including orange, red, pink, maroon, brown, chocolate, blue and black, and are produced by the combination of various dianzo-bodies with phenols, the most important of which latter is β-naphthol (beta-naphthol).

In practice their application is briefly as follows:—The bleached cloth is prepared in a solution of β-naphthol in caustic soda (naphtholate of soda), then gently dried and printed with the thickened diazotized amine required to produce the desired shade. The printing colour must be cooled with ice to prevent its decomposition; hence such colours are sometimes known as "ice colours."

The two colours most extensively used are para-nitraniline red and α-naphthylamine maroon, both of which are bright fast colours, only equalled by turkıey red and madder chocolate for general usefulness.

On β-naphthol prepare the following colours may be obtained:—

Red with paranitraniline.
Maroon with α-naphthylamine.
Orange with orthonitrotoluolide.
Pink with azo pink 2 B.
Chocolate with benzidine.
Brown with benzidine and orthonitrotoluolide.
Blue with dianisidine.
Black with dianisidine and benzidine.

Other naphthols and other bases give a still greater variety of shades.

The β-naphthol prepare requires to be freshly made, and the cloth prepared with it carefully dried, if good results are to be obtained.

Para-nitraniline is made up for printing by dissolving in hydrochloric acid. Nitrite of soda is then added, and, after standing a short time to complete the reaction, the resulting diazo-solution is mixed with thickening, and acetate of soda is then added to neutralize any free mineral acid still remaining, the presence of which would prevent the formation of the colour.

In practice the following formulae have given good results:—

(1) Para-nitraniline Red

Prepare the bleached cloth in:—

47 parts β-naphthol
3 napthol R.
107 caustic soda, 50° Tw.
400 hot water.
10 tartar emetic.
12 tartaric acid.

Make up to 1000 parts with hot water.

The cloth is passed through a trough containing this solution, and the cloth is gently dried and then printed with:—

36 parts paranitraniline C.
100 ice.
100 hydrochloric acid, 30° Tw.
70 water.

Mix and add quickly:

24 parts nitrite of soda, 93 per cent.
70 water (cold).

And just before printing add further:

100 parts acetate of soda.
100 ice in large pieces.
400 tragacanth mucilage, 12 per cent.

Print, dry and wash.

A similar prepare without the naphthol R. may be used for α-naphthylamine maroons, the printing colour for which is made up as follows:—

36 parts α-naphthylamine.
93 hydrochloric acid, 50° Tw.
171 tragacanth mucilage.

Grind till perfectly smooth in a mill and then add:

100 parts ice.
20 nitrite of soda of 93 per cent. strength.
80 water.
400 starch and tragacanth thickening.
25 benzine.
75 acetate of soda.

Print, dry and wash.

Immediately these diazo-colour pastes come in contact with the naphthol-prepared cloth the colour is formed and fixed and requires no further treatment except that of washing to remove the naphthol from the unprinted parts of the cloth.

The other bases are diazotized in precisely the same way, the quantities of acid and nitrite of soda being varied according to the molecular weights of each base.

Several processes of printing azo-colours directly, without any previous preparation of the cloth, have been proposed, but they are not in general use as yet; those which have passed the experimental stage are not very successful on the large scale, and have, for the most part, been abandoned.

(g) Application of Sulphur Dyes.—Of late years the class of colours known as "sulphur colours" have assumed a prominent place in textile-printing. They are really direct dyes, but their special properties entitle them to be classed apart from those usually known under this name.

There are now an enormous number of sulphur-colours on the market under many different names, but, as they are all similar in general properties, it is needless to mention more than one series.

The "Meister" colours of Messrs. W. H. G. Meister, Lucas and Bruening will serve as well as any to exemplify the application of these dye-stuffs in printing. They comprise yellows, golds, browns, violets, blues, greens and blacks, all fairly, and some very, fast to light and soap, and, under proper conditions, easy of application to a variety of styles.

The general recipe for printing is as under:—

30 parts by weight of colouring matter.
50 water.
50 china clay beaten up with water.
50 water.
40 concentrated hydro sulphonyte N.F., 50 per cent. solution.
700 alkaline British gum thickening.

This paste is printed on unprepared bleached cloth, gently dried and then passed through a rapid steam aper, in from 4 to 7 minutes in dry steam at 212° F. to 220° F. (or twice for 3 minutes), after which the cloth is passed up open width through the washing and soaping machines, and finally dried up and finished.

The sulphur colours may be used in combination with the azo-colours, on naphthol-prepared cloth, for the production of multi-colour effects, and are eminently adapted also to the production of coloured discharges on paranitraniline red and the direct-dyeing colours.

(b) Aniline Black.—Aniline black was discovered and first used by Lightfoot in 1863. It is one of the fastest blacks known, and is equally useful for direct printing by itself, and for working along with printed mordants and discharge pastes. Aniline black is formed by the oxidation of aniline.

As a rule the oxidation of the aniline is brought about by means of sodium chlorate in presence of suitable oxygen carriers such as copper sulphide, vanadium chloride or potassium ferrocyanide. Copper and vanadium blacks are usually developed after printing by being aged in a moderately warm room for a day or two, when they become converted into "emeraldine," at which stage they are taken down, and passed through a hot solution of bichromate of potassa, complete the oxidation of the aniline. Great care is required in printing these two blacks, as if overdried they take fire and have occasionally caused considerable damage to buildings in consequence. The blacks made with ferrocyanide, on the contrary, will be printed in conjunction with "steam" colours, and, after a preliminary passage through a rapid steam aper, and an ammonia gassing box, will withstand the long steaming necessary for alizarin colours.

A copper aniline black may be made as follows:—

15 lb. starch.
8 lb. British gum or dextrine.
5 gal. water.
4 lb. chlorate of soda.
4 gal. olive oil.

Boil, cool and add:

8 lb. aniline salt.
3 lb. aniline oil.
5 lb. sulphide of copper (precipitate pressed to a 30 per cent. paste).
1 gal. water.
This black may be either hung to develop, which is the safer course, or it may be treated with gentle steam for 2 to 3 minutes. Whichever method is adopted the printed cloth must afterwards be passed through hot bichromate—"chroming"—and then well washed.

The following Van Dyke black works well in practice:

- 10 lb starch
- 2 lb British gum
- 6 lb yellow prussiate (ferrocyanide) of potash.
- 7 gal. water.

Boil, turn off the steam, and add:

- 2 lb chlorate of soda in powder.
- Cool and add:
- 8 lb aniline salt.

Print, age 4 minutes through the rapid ager, chrome, wash and soap. If printed with alizarin steel colours it must be passed through ammonia vapour after ageing, and then be steamed for one hour before chrome and washing. Sometimes the chroming is omitted, but the colour is then apt to become green after a short time owing to the action of sulphur dioxide present in the air.

Aniline black is now used almost exclusively for printing along with mordants for the madder style, and for black ground goods that were formerly dyed with logwood on an iron mordant. Shirts and all single-colour black dress goods are also executed in aniline black, which is faster to light, washing, and perspiration than the old style except some of the sulphur blacks.

(2) **Printing of Mordants.**—This, the second of the great styles of textile printing, was, at one time, the most extensively practised of all, and is still the most important for all classes of goods where the fastest colours are required. It may be conveniently divided into two branches: (a) the madder style, and (b) the printing of other mordants such as chrome, tannic acid, beta-naphthol, &c.

If they are too low, the style only the mordants used are those of aluminium and iron.

Aluminium alone yields various shades of red and pink when dyed up in madder, or its artificial competitor alizarin. Iron alone yields with the same dye-stuffs shades varying from black to the palest lavender. Iron and aluminium mordants in combination yield colours ranging in shade from claret through all gradations of brown, and are the deepest colours, according to which of the two mordants predominates in the mixture. Browns and allied colours may be dyed on the same mordants with either nitroalizarine alone, or with alizarine itself mixed with dyewood extracts—logwood, Persian berry or quercitron bark, &c.

Both aluminium and iron mordants consist of the acetates of their respective metals. The iron mordant which gives the best results is known as "black liquor." It is a crude acetate containing a good deal of organic matter which appears to regulate the speed of its oxidation and so produce much more level colours than have ever been obtained from any other iron mordant.

Aluminium acetate in the pure state is also rarely employed, the crude commercial "red liquor" being found in practice to yield the best results, both as regards colour and ease of working.

The "red liquors" vary considerably in composition, some being normal acetates, others basic acetates, some normal sulphate-acetates, others basic sulphate-acetates, but their mode of application is always the same, that is, they are thickened, printed, aged and dyed as follows:—

(1) After printing the cloth must be thoroughly dried, otherwise the mordants become dehydrated or "burnt," and instead of dyeing up evenly they appear patchy and very light in the overdried parts; and ordered most of them may be surmounted; (2) after printing the cloth must be quite dry, otherwise the mordants become dehydrated or "burnt," and instead of dyeing up evenly they appear patchy and very light in the overdried parts; and ordered most of them may be surmounted; (3) the temperature of the dye-bath must be kept as low as is consistent with the fixation of the colour. If these last two points are neglected the unprinted parts of the cloth, which should remain a pure white when it is finished, will be soiled beyond repair unless instead the "whites" are cleared at the expense of weakening the colour. Iron mordants especially are liable to unevenness due to the oxidation being too rapid, and as this deficieney is noticeable in purples and lavenders, the pyrogallic of iron or "black liquor" is frequently boiled for half an hour or more with 1 per cent. of its weight of arsenious acid, or "white arsenic," a substance which either aluminium or iron acetates, and hung or "aged" for 2 to 3 days in a brick chamber containing moist air at about 30° C. dry bulb, and 27° C. wet bulb thermometer. In this operation the "aging" (which is really the volatilization of the pyrogallic acid, leaving the hydrated oxide on the fibre) goes on slowly and evenly. After hanging, the last traces of acid are removed and the hydroxide thoroughly fixed by "dunging," a process in which the goods are passed through a mixture of cow-dung and chalk at a temperature of about 50° C. In this "dunging" bath they are worked altogether about 1½ hours, at the end of which the mordants are thoroughly fixed, and all the thickening agents perfectly eliminated, thus leaving the cloth in the best condition to absorb the dye-stuff.

The dyeing is carried out by working the goods at 60° C. in a mixture of alizarine, a little chalk, and glue size for 1 to 1½ hours. They are then washed, soaped, and the whites cleaned by a passage through weak bleaching powder solution, followed by a passage through steam. Further soaping and washing is then resorted to until the goods are quite clear and bright.

In the case of cloth dyed in red and pink alone the goods after dyeing are well washed, passed through a bath of alizarine oil containing oxalate of ammonia, and then steamed for one hour at 15 lb pressure. This brightens the colours by removing the brown appearance they possess after dyeing. When reds are associated with chocolates and purples, however, the oiling process must be carefully conducted, otherwise the two latter suffer; frequently it is left unaltered altogether, the brightening being effected by vigorous soaping.

By printing the following mordants a six-colour design may be produced with a single dye-stuff and in one dyeing:

The above mordants are printed on white bleached cloth, dried, hung 2 to 3 days, "duged," dyed, washed, well soaped and washed again; then "chemicked" through weak bleaching powder solution and finished.

The "dunging" is performed in vats through which the cloth circulates continually during the operation. As a rule dunging is done twice, the second bath being weaker than the first. The vats or "becks" contain a mixture of:

- 100 gals. water
- 10 lb chalk
- 50 lb cow-dung

At 60° C.

- 190 gals. water
- 5 lb chalk
- 25 lb cow-dung

Wash well after "dunging" and dye in alizarine, &c.

The dyeing is carried out in large becks over which a roller or bowl revolves, equal in length to the beck. Over this roller the cloth is wound spirally in large loose loops so that one end of the loop is on the roller and the other dips into the dye liquor. When about 990 yds. of cloth have been entered in this way the two ends of it are knotted together, thus forming an endless rope which circulates continuously in and out of the dye liquor. The vat or beck is then charged with alizarine, chalk and glue, the proportions varying according to the amount of space covered by the mordants on the cloth. If, for instance, half the surface is printed then the dye-liquor might be made up as follows, the quantities being calculated on the weight of the cloth:

- 4 per cent. alizarine (blue shade), 20 per cent. in a sufficiently
- 11 gal. acetate of lime, 28° Tw.
- 10 glue solution, or size, 15 per cent. of water.

The goods are entered into this solution cold. The temperature is gradually raised to 60° C., and the dyeing continued at this for one hour. The cloth is then washed in a similar machine, soaped well and finished off by drying.

Aniline black may be printed along with "red liquor" and iron liquor, and many other modifications also employed, but the principle of dyeing is always the same.

(b) **The Printing of Other Mordants.**—Of these the most important are tannic acid, chrome mordants and beta-naphthol.

For printing tannic acid, the following is used:

- 5 lb tannic acid dissolved in 1 gal. acetic acid and added to 9... starch and tragacanth paste.
The goods are usually dried after printing and the tannic acid immediately fixed by passing through a solution of—

\[ \text{2 oz. tartar emetic.} \]
\[ \text{1 oz. chalk.} \]
\[ \text{1 gal. water at } 60^\circ \text{C.} \]

After washing they may be dyed up in any of the basic anilne colours.

Various chrome mordants are employed in printing, amongst which may be mentioned chromium chloride, and chromium acetic. The former is thickened with starch or gum, printed, and fixed by being passed through boiling sodium carbonate. The latter is applied in the same way but, after printing, is steamed before the carbonate treatment. Both these mordants are suitable for dyeing with any of the dyes mentioned under the direct printing of mordant dyed goods such as azoic, alizarine bordeaux, coeruleine and the natural dye-wood extracts. They are dyed similarly to the madder colours, with an addition of glue size to preserve the white of the unprinted parts of the cloth.

(3) The Style—This style is now one of the most important produced. Its range is so extensive, and its modifications so numerous, that it is impossible to mention more than a few of its characteristics. It may be used for locally destroying either the colours dyed on cloth, or the mordants with which they have been previously prepared. In both cases the resulting pattern appears in white, or colours, on a full rich ground the beauty of which is enhanced by direct printing.

The discharging agents consist of organic acids, caustic alkalis, oxidizing agents and reducing agents, each used according to the kind of colour or mordant to be discharged.

(a) Discharge of Iron and Aluminium Mordants.—The cloth is padded with a solution of these mordants, dried in hot air, and then printed with thickened citric acid or acid citrate of soda mixed with starch or gum in clay to prevent the pattern from running. It is then passed through the rapid ager once or twice, "duggered," washed, and dyed in the usual way for madder colours. Wherever the discharge has been printed the mordant is dissolved out, leaving a white pattern on a dyed ground.

(b) Tannate of antimony mordant is similarly discharged by printing on caustic soda. The goods are passed in like manner through the ager, well washed in water, and dyed-up in any basic aniline dye.

(c) The chrome discharge is produced by padding the goods in chromium bisulphate; then drying them, and printing-on citric acid, or chloride of soda and yellow prussiate of potash. They are then steamed, passed through chalk and water, well washed and dyed up in any mordant dye.

(d) Turkey red may be discharged in both white and coloured patterns by either oxidizing agents or caustic alkalis. (1) The dyed cloth is printed with strong citric acid, or acetic acid, at 180° Tw., and then run through bleaching powder solution, whereby the printed parts are completely decolorized. If colours are required, the citric acid is mixed with lead salts and Prussian blue, and the fabric after passing through the bleaching powder solution is further treated in a bath of bichromate of potash which forms with the lead salts the insoluble chrome yellow. Green is obtained by the combination of Prussian blue with the chrome yellow.

Examples:

**White.** 6 lb citric acid or tartaric acid. 1 gal. water. 4 lb British gum or dextrine. Boil together.

**Yellow.** 15 lb British gum. 1 gal. dark British gum paste, 30 per cent. 2½ gal. water. 20 lb tartaric acid. 12 lb nitrate of lead.

Print, dry, discharge through bleaching powder solution, 18° Tw., and chrome.

(2) The dyed cloth is printed with strongly alkaline discharge pastes, passed through the ager "twice or three times, and then washed off in silicate of soda. If blue, yellow and green discharges are desired the dyed cloth must first be passed through glue solution, well dried, printed with the colours, "aged," passed through silicate of soda, chromed in bichromate, well washed and dried. Examples:

**White.** 10 lb stannous chloride dissolved cold in 8 gal. alkaline thickening. 2 lb silicate of soda, 70° Tw.

**Blue.** 15 lb indigo pure 20 per cent. paste. 1 gal. turpentine. 7½ gal. water. 8 lb, 6 parts of the yellow. 1 lb blue.

**Yellow.** 30 lb lead hydrazine 50 per cent. paste, 24 gal. water. 2½ gal. silicate of soda. 1 lb, 6 parts of the yellow. 1 lb blue.

**Green.** 8 parts of the yellow. 1 lb blue. 7½ gal. water. 1 lb bichromate of potash. 1 gal. turpentine. 1 lb bichromate of potash. 8 gal. silicate of soda, 100° Tw.

**Red.** 15 lb indigo pure 30 per cent. paste. 24 gal. water. 2½ gal. silicate of soda. 1 lb, 7½ gal. water. 1 lb bichromate of potash. 7½ gal. water. 1 lb bichromate of potash. 7½ gal. water. 1 lb bichromate of potash. 7½ gal. water. 1 lb bichromate of potash. 7½ gal. water. 1 lb bichromate of potash.

(f) *Prana-traniline red* is discharged by means of the new hydro-sulphite-formaldehyde compounds. The dyed cloth is printed with the following:

- 25 lb hydro sulphite N.F. conc., or hydroaldite conc.
- 14 lb British gum paste.
- Heat till dissolved and add—
  - 2½ lb glycerin.
  - 1 gal. starch-traganath thickening.

After printing, age twice for 4 minutes through dry steam at 220° F., then wash well and soap.

Coloured discharges are obtained by mixing hydro sulphite, tannic acid, aniline or phenol, and basic colouring matters together. Mordants fixed with chromium acetic may also be used.

On a-naphthylamine maroon the above discharge white requires the addition of indoline scarlet, patent blue or anthraquinone, if it becomes effective, otherwise the procedure is the same as for prana-traniline red.

(g) Indigo is usually discharged by oxidation. For this purpose the dyed cloth is printed in two different ways. Firstly, with chloride of soda, and red or yellow prussiate of potash together with a little citric acid or citrate of soda; secondly, with chrome of potash. In the first instance, the cloth is "aged" through the rapid ager after printing, and, in the second, is passed through a vat containing hot sulphuric and oxalic acid. Coloured discharges may be obtained in both methods by adding albumen and pigment colours to the discharging agents.

(1) Discharge by steaming—

- 12 lb citric acid, dissolve in:
  - 7 lb caustic soda, 70° Tw., and add
- 12 lb sodium chloride.
- 5 gal. British gum paste.
- Heat till dissolved, cool and add—
- 1½ gal. British gum paste.
- 2 lb yellow prussiate of potash.

Print, steam and wash.

Chlorate of aluminium is also used for this process, but it acts very energetically and is apt to tender the cloth.

(2) Chromate discharge.

**White.** 8½ gal. British gum paste. 12 lb bichromate of soda. ½ gal. turpentine.

**Yellow.** 32 lb chrome yellow pigment.
- 3 gal. 50 per cent. albumen solution.
- 1 thick tragacanth mucilage.
- ¼ oil (vegetable).
- 12 lb bichromate of soda neutralized with
  - ¼ gal. caustic soda, 70° Tw.
  - 1½ gal. water.

Print, dry, pass through a "beck" (i.e. a bath) containing—

- 100 gal. water.
- 50 lb sulphuric acid (168° Tw.).
- 50 lb oxalic acid.

Then wash and dry.

With these oxidation discharges it is impossible to prevent the fibre being attacked in the bleached portions, with the result that it is partially converted into oxycellulose. Recently a method has been brought out for the production of a white discharge on indigo which is said to do away with the formation of oxycellulose and which consists of a thickened solution of sodium nitrate and, after drying, running through sulphuric acid of 50° Tw.

Another method of producing white discharges on indigo consists in printing the dyed cloth with hydrosulphite N.F., then steaming and running through a boiling solution of caustic soda. Good whites are thus obtained without the formation of oxycellulose, but the process is expensive.

(h) Direct dyeing or substantive colours can be easily discharged with the hydrosulphite discharge used for prana-traniline red (see above). It must be reduced in strength to about one-fourth for dark shades, and much weaker for lighter colours. Direct colours were formerly discharged by stannous chloride or acetate, but the hydrosulphite has almost entirely displaced these salts for white discharges.

Discharges on manganese bronze are of little importance at the present time. They are effected by means of stannous chloride, colours being obtained by the addition of basic dyes and dyewood extracts.

(1) Sulphur-colours, dyed basic colours, and some alizarine colours, are discharged with chloride and prussiate like indigo.

(2) The Resist or Reserve Style.—Reserves are substances which, when printed, prevent the fixation or development of mordants and colours subsequently applied, and are used to produce effects similar to those obtained by discharge printing.

The principal reserves are those used for madder dyed goods, such as alizarine reds and pinks, basic alkanes, vat indigo blue, insoluble azo colours, sulphur-colours and aniline black.
(a) *Reserves under Aluminium and Iron Mordants.*—For the production of this important class of goods, use is made of all the citrates, of which the Mordant prevents the fixation of the mordant. The cloth is first printed with citrate of soda (or sometimes citric and tartaric acids for iron mordants), then dried and again printed over the resist impression, with either a fine "all over" pattern or flat uniform ground, in iron or aluminium mordants. The fabric is then aged, "dug," washed and dried, as already described, with the result that whatever the "reserve" or acid of acid was printed a white pattern is left on a figured or plain ground. The fine patterns printed over the "reserves" are called "cover and pad" style in cases where, as frequently happens, a dark "cover," and a light "pad" are both printed over a white "reserve." The "cover and pad" style is, for the most part, restricted to dyed alizarine purples under which red, black, dark purple and white can all be reserved at the same time, thus giving rise to very pleasing effects. For example: white cloth is first printed with four "colours," viz. citrate of soda and acid for the white; logwood and iron for the black; strong iron mordant for the purple; and aluminium acetate at 6° Tw. with 8 oz. per gallon of stannous chloride for the red. (The stannous chloride acts as a resist for iron mordants.) The whole is then "covered" in a fine pattern printed in a strongly iron mordant, dried, and again printed, in a very weak iron mordant, with a pad roller, that is, a roller which rolls a uniform ground over the whole surface of the cloth. After this last printing, the cloth is "aged" for a day or two, by being hung as previously described, then "dug," washed and dried. This "cover and pad" style of reserve printing constitutes one of the staple processes of nearly all print-work, and is produced in enormous quantities for both home and foreign markets. Red is not often introduced as in the above example, the usual colours being white, black and two purples. The same method of working can be adopted with aluminium mordants for red and pink covers and pads, but they are better produced with the steam alizarine colours as below.

(b) *Reserves under Steam Alizarine Red and Pink.*—In this case a reserve composed of citrate of chromium alum, or in conjunction with citrate of soda, gives the best results. The goods are first prepared in the usual manner and then printed with the following:

As Make up to 10 gals. 10 gals. 10 gals. 10 gals.

Potassium sulphite is also used as a white reserve under insoluble azo-colours with good results.

(4) *Reserves under Steam Basic Colours.*—The white cloth is printed with:

- 20 lb China clay.
- 2½ gal. water.
- 1½ lb British gum.
- 20 lb Sodium tartaric emetic.
- 20 lb Zine sulphate.

All boiled well together, and then covered, or over-printed, with any steam basic colour—steamed one hour, passed through tartar emetic, then washed and soaped, when the reserve white comes away, bringing along with it the colour printed upon it and leaving a white pattern on a printed ground.

(5) *Reserve under Vat Indigo Blue.*—This was formerly a very important style, but at present is only used in special cases. Resist or reserve effects are obtained by painting the white cloth with oxidizing agents, &c., and subsequently dyeing it in the indigo vat. In addition to oxidizing agents the reserve pastes contain lead sulphate, barium sulphate, resins, fats and thickenings in various proportions. The following is a good white reserve:

- 15 lb flour.
- 6 gal. water.
- 18 lb Copper sulphate powdered.
- 2½ gal. Copper nitrate, 96° Tw.
- 1 pint Alizarine oil.
- 2½ gal. British gum paste.
- 52 lb Lead sulphate, 66 per cent. paste.
- 18 lb Zine sulphate.
- 2 lb Lead nitrate.

Print the white and yellow, dry, dye in the indigo vat—sour slightly in sulphuric acid, wash, and pass into a hot solution of bichromate of soda, which develops the lead yellow. Reserve whites also contain lead salts when used for white alone, but obviously the white given is best suited to white and yellow reserves, as it is soluble copper salts wash out before the "chroming" stage is reached.

(6) *Reserves under Sulphate Colours.*—These are obtained with zinc chloride. They are not much used, but are capable of yielding fine effects.

(7) *Reserves under Aniline Black.*—Reserves under aniline black are produced with caustic alkalis, alkaline carbonates, bicarbonates and sulphites, sulphocyanides, oxide of zinc and the acetates of magnesium, zinc and soda. The white and coloured resists may be printed upon either the undeveloped black or upon the cloth before the black is applied.

In the former case the cloth is slow-padded through a mangle-box with the following black:

- 7½ lb Aniline hydrochloride.
- 3½ lb Sodium chloride.
- 4 lb Potassium ferrocyanide.
- 10 gal. water.

It is then very carefully dried in hot air so that it becomes no darker than a pale yellow; if it is green before printing, the white is sure to be bad.

The dried padded cloth is then printed with the "resist" colours, dried and steamed 3 to 4 minutes in a rapid ager, chromed through warm bichromate of potash, and finally washed and soaped. During the steaming the black is developed all over the cloth except where the colours are printed. Here its development is prevented by the alkali or the reducing agent, whichever may be present, in the colour, and instead of a plain black dyed piece a coloured design on a black
TECHNOLOGY | TEXTILE-PRINTING

Ground is produced. The following formulae may be employed for white and coloured resists:

**White.** 8 lb starch, 8 lb British gum, 30 lb potassium sulphite, 90° T. w., 3 gals. water, 15 lb soda acetate, 10 lb bisulphite of soda, 66° T. w., ¼ lb ultramarine blue.

Boil together.

| Rhodamine 6 G. (100 per cent.) | 2½ lb | 1 lb | 2 lb | 2 lb | 2 lb |
| Auramine O | 2 lb | 1 lb | 1 lb | 1 lb | 2 lb |
| Acridine yellow G. | 2 lb | 1 lb | 1 lb | 1 lb | 2 lb |
| Thiochrome blue B. | 2 lb | 1 lb | 1 lb | 1 lb | 2 lb |
| New solid green 2 B. | 1½ gals. | 1½ gals. | 1½ gals. | 1½ gals. | 1½ gals. |
| Methyl violet, B. x. | 1 gal. | 1 gal. | 1 gal. | 1 gal. | 1 gal. |
| Water | 6 | 6 | 6 | 6 | 6 |
| Tragacanth mucilage | 1 gal. | 1 gal. | 1 gal. | 1 gal. | 1 gal. |
| Glycerin | 1 gal. | 1 gal. | 1 gal. | 1 gal. | 1 gal. |
| Albumen, 40 per cent. solution | 4 lb | 4 lb | 4 lb | 4 lb | 4 lb |
| Resist paste | 6 lb | 6 lb | 6 lb | 6 lb | 6 lb |

Print on the padded cloth, age, chrome and wash. The resist paste is as under:

**Resist Paste.** 10 lb zinc oxide, 1 gal. magnesium acetate, 40° T. w., 1½ lb tragacanth mucilage (dragon), 1½ lb starch paste.

For reducing the colours take 6 parts resist paste, 4 lb starch paste, 4 lb white resist.

Very good results can be obtained by the alternative method, i.e. printing the resists on white cloth and applying the black afterwards. The basic colours are chiefly used, though chrome yellow and ultramarine are also employed for some styles. The following formulae will serve as types of the composition of white and colours:

**White.** 20 lb precipitated chalk, 5 lb potassium sulphite, 90° T. w., 5 lb acetate of soda, ½ lb ultramarine blue for lightening, 1 gal. water, 6 lb starch paste.

The whole ground together in a mill.

**Colour.** 2 lb basic dye-stuff, 1 gal. water, 2½ lb starch paste, 17 lb zinc oxide, 1 gal. water, 1 lb glycerin, 1 lb turpentine, 1 lb bisulphite of soda, 1 lb starch paste.

Print on white cloth, allow to lie a day or two, then drop-pad in the Prudhomme black already given, dry, age, chrome and soap.

Pigment colours may be applied on black padded cloth as follows:

**Yellow.** 40 lb chrome yellow, &c. &c., 2½ gals. 90 per cent. albumen, ½ gal. tragacanth water, 6 oz. per gal, 6 lb soda ash, 1 gal. citrate of soda, 40° T. w.

Other methods, varying in detail, have been used from time to time, but the above two are at the present time generally employed especially the former, by which many fine patterns have been produced in all sorts of delicate and artistic shades.

*The Treatment of Cloth after Printing.*

After printing, the various classes of goods undergo many different treatments according to the character of the colours printed. These treatments include steaming, hanging in the ageing chamber, passing through tartar emetic, the chalk bath, washing, soap-dimming, clearing, and finishing.

1. The operation of steaming is necessary for all styles except those with the insoluble azo-colours, vat dyes discharged, and some colours that are precipitated on the fibre. The short steaming necessary for most discharges, indigo blue prints, and aniline black is effected in the Mather and Platt ager, of which a sketch is here given (fig. 2) showing its principle.

2. When the latter is fully loaded in this way it is run into the cottage, the doors are closed, and steam turned in. The steaming is continued for various periods of time—from ½ hour to 2 hours—according to the style of work in hand, and either with or without pressure, as may be required. The cottage is then withdrawn and the goods unwound in readiness for subsequent operations.

The object of enveloping the printed goods in a "back grey," is to prevent the colour from marking off from the face of one fold onto the back of the next, and also to minimize the risk of damage from drops of condensed water. This latter defect is further guarded against by heating up for an hour or so every morning before any goods are introduced.

In works where the modern continuous steaming apparatus is installed the cottage steamer is reserved for the treatment of dyed alizarine and rose woods, such as heavy printed velvets, which are difficult to manipulate in the continuous steamer.

*The continuous steamer was originally invented by Cordillor, but its present efficient form is due to Messrs. Mather and Platt, who have continually improved it, so that now it bears little resemblance to Cordillor's original machine. Its construction is too complex to be adequately described without the aid of detailed sketches. Generally speaking, it may be said to consist of a long,
TEXTILE-PRINTING

TREATMENT.

high, narrow chamber of brick, through which the cloth passes continuously. The remaining and temper of the soap solution, the duration of the soaking and the type of machine used are all varied according to the fastness of the colours to be soaped. As in washing, the alizarine dyed colours, alizarine steam and pink, alizarine black, and various shades of these dyestuffs are, not only difficult to soap, but require strong soaping, but are greatly brightened and enhanced in beauty thereby. On the other hand, direct dying colours, basic colours, pigments, and a few of the other classes of colouring matter are easy to be soaped in the open width. Colours which will stand a drastic soaping are usually sooped in spiral becks, in the rope state, and pass from one to another of these becks, going through as many as half a dozen or more, soaping off in warm water. Great care must be used to be soaped in the open width are treated in a special soaping machine known as the "open soaper." It is in principle this is simply a range of watertight boxes each fitted with rollers at the top and bottom. Two boxes are in solution and the rest hot or cold water or a series of spirit pipes to better wash out the soap. Very frequently open soopers are supplied with "tartar emetic" and "curing" brines so that the goods can go through two or more processes directly and without any intermediate handling.

Chemicking:—In this process all traces of colour still remaining after soaping are removed from the white parts of the printed cloth, by a weak solution of bleaching powder. Two methods are used in applying the "chemick," or bleaching powder solution, to the cloth. In the first the cloth is passed through a pair of boxes into which the cloth is partly immersed in a solution of bleaching powder or "chemick" varying in strength from ¼% to ¾%. This lower bowl carries the chemick to the cloth, the upper box is the same as the lower and the cloth goes forward over a set of steam-heated drying cylinders, during its passage over which the bleaching properties of the chemick effectively remove the last traces of colours from the white parts of the cloth and leave it perfectly clean and bright.

The second method of "Chemicking" is employed when the cloth is too deeply stained to be successfully "cleared" by the first. All the colour-dyed goods, and goods printed in strong heavy dark-coloured patterns, are liable to attract, to their white parts, a considerable amount of colour during the dyeing, washing and soaping operations. This is a very serious matter in Chemicking, and this is the second method supplies. The goods are passed successively through (1) a trough containing "chemick" at about 1½% Tw.; (2) a pair of squeezing rollers; (3) a small steam box fitted with half a dozen guide rollers top and bottom, and a steam admission pipe; (4) a series of "spirit pipes" to wash out the bulk of the lime salts; and (5) through a washing-box and squeezing rollers, whence they go directly to a drying machine.

In both methods the strength of the "chemick" depends upon the power of the resistance to its action of the colours printed, and great care must therefore be taken to keep it correct.

Occasionally a little ultramarine blue is added to the chemick for the purpose of correcting the yellowish tinge usually possessed by bleached cotton.

In both methods the strength of the "chemick" depends upon the power of the resistance to its action of the colours printed, and great care must therefore be taken to keep it correct.

Fig. 7.—Portion of reddish linen lining for a cassock printed in black from wood blocks, with a repeating pattern composed of five-lobed shapes enclosing conventional fruit device surrounded by small blossom and leaf forms. Rhineland, 19th century; from the neighbourhood of Düsseldorf. 4 ft. 8 in. x 2 ft. 3 in.

Fig. 8.—Cotton print in colours. Dutch, 17th century. About 4 ft. x 9 in.

Fig. 9.—Portion of a coverlet of cotton, printed at Genoa in colours, from metal plates engraved with trees, flowers, birds, and animals in the style of Italian palampores or printed calicoes. 19th century. About 6 ft. x 3 ft.

Fig. 10.—Portion of a hanging of cotton, printed in red from metal plates engraved with repetitions of pictorial scenes. At the bottom is printed "D. T. F. Mettler & Cie de Beaumari près Bordeaux; Bon Teint. MF. S. X. Comm. 1805." French, second half of 18th century. 4 ft. 6 in. x 3 ft. 4 in.

Fig. 11.—Portion of a chair back, printed in red from a metal plate engraved with a Chinese pagoda in a landscape in front is a woman kneeling on the ground, while a priest stands to the left holding up an image. Marked "Collins Woolmers." English, dated 1795. 2 ft. 4½ in. x 2 ft. 4½ in.

Fig. 12.—Linen panel, with a stipple engraving printed in colours, for use as a small fire-screen. English, late 18th century. 2 ft. 4½ in. x 2 ft. 3½ in.
“stentering” machines. On these machines the draped cloth is carried forward, over steam-heated drying plates, by two travelling endless chains, each link of which is constructed to clip the selvedge of the cloth. The distance apart of these chains can be regulated to suit the width of cloth and width of travelling plates. When they diverge, so that as the cloth advances it gradually becomes stretched out to the required width and is dried at the same time to prevent it contracting when it is released from the pull of the chains, as it leaves the machine.

Finally the goods are cut into certain lengths, wound round flat boards, tied up, ticketed and packed.

Wool-Printing.

The printing of wool differs little from the printing of cotton in general. Most of the colours employed in the one industry are used in the other, and the operations of steaming, washing and soaking are almost identical.

Unlike cotton, however, wool requires to be specially prepared, after bleaching, if the full tintorial value of the colours is to be obtained.

Two quite different methods of preparation are resorted to, namely (1) the chlorination of the wool; and (2) the precipitation of stannic acid on the fibre. In the first method the woollen fabric is first passed through a solution of bleaching powder, then well squeezed without washing, put into dilute sulphuric or hydrochloric acid, squeezed again and well washed in water, after which it is dried. Great care and experience are demanded in this operation to prevent the wool from becoming hard and yellow.

In the second method the cloth is first boiled in stannate of soda, well squeezed, passed into dilute sulphuric acid, well washed and dried. For certain styles of work it is necessary to combine both preparations.

Although alizarine, mordant colours and dyewood extracts can be used on wool, the vast majority of patterns printed on wool are executed by means of acid dye-stuffs and basic colours, for both of which this fibre possesses a natural affinity and therefore these colours are simply dissolved in a little acetic and citric acids, thickened with gum and printed without any further addition. The addition of tannic acid, however, can be made to, and probably increases the fastness of the basic dyes. Mordant colours like logwood black are applied in the usual way.

The printing of wool is carried out exactly as for cotton, but if the fabric is to be obtained, the engraving of the roller must be deep, the blanket on the machine as soft as possible, and the drying of the printed cloth very gentle. After printing, the goods are steamed in moist steam or wrapped between moistened “greys” and steamed in a “cottage” steamer. If too little moisture is given, the colours lack both strength and brilliancy; if too much they run. The correct degree of dampness can only be determined by experience of the work, combined with a special knowledge of the particular apparatus employed.

After steaming, the printed goods are washed in plenty of water, then dried up and finished with a little glycerin or some waxy preparation.

Discharges may be very easily obtained on wool dyed in acid dye-stuffs, by means of stannous chloride and basic colours for the coloured effect, and hydro sulphite for the white.

Silk-Printing.

Silk-printing calls for no special mention. The colours and methods employed are the same as for wool, except that in the case of silk no preparation of the material is required before printing and the ordinary dry “staining” is preferable to damp “staining.”

Both acid and basic dyes play an important rôle in silk-printing, which for the most part is confined to the production of articles for women—dress goods, handkerchiefs, scarfs, and shawls—articles for which bright colours are in demand. Alizarine and other mordant colours are mainly used, or ought to be, for any goods that have to resist repeated washings and prolonged exposure to light. The use of basic dyes frequently requires to be preceded in alizarine oil, after which it is treated in all respects like cotton—steamed, washed and soapd—the colours used being the same.

Silk is especially adapted to discharge and reserve effects. Most of the acid dyes can be discharged in the same way as when they are dyed on wool; and reserved effects are produced by printing mechanical resists, such as waxes and fats, on the cloth and then dyeing with spirit-liquor. The great affinity of the silk fibre for basic and acid dye-stuffs enables it to extract colouring matter from cold solutions, and permanently combine with it to form an insoluble lake. After dyeing, the reserve prints are washed, first in cold water to get rid of any colour not fixed on the fibre, and then in hot water or benzene, &c., to dissolve out the resisting bodies.

As a rule, after steaming, silk goods are only washed in hot water, but, of course, those printed entirely in mordant dyes will stand soaping, and indeed require it to brighten the colours and soften the material.

II. Art and Archaeology

Printing patterns on textiles whether of flax, cotton or silk, by means of incised wooden blocks, is so closely related in its ornamental effects to other different methods of similar intention, such as by painting and by processes of dyeing and weaving, that it is almost impossible to determine from the picturesque indications afforded by ancient records and writings of pre-Christian, classical or even medieval times, how far, if at all, allusion is being made in them to this particular process. Hence its original invention must probably remain a matter of inference only. As a process, the employment of which has been immensely developed and modified in Europe during the last hundred years by machinery and the adoption of stereotypes and engraved metal plates, it is doubtless traceable to a primeval use of blocks of stone, wood, &c., so cut or carved as to make impressions on surfaces of any material; and more the existence of these can be traced in ancient civilizations, e.g. of the Chinese, Egyptians and Assyrians, there is a probability that printing ornament upon textiles may have been practised at a very early period. Nevertheless, highly skilled as the Chinese are, and for ages have been, in ornamental weaving and other branches of textile art, there seem to be no direct evidences of their having resorted so extensively to printing for the decoration of textiles as peoples in the East Indies, those, for instance, of the Punjab and Bombay, from whose posterity 16th-century East and especially Dutch merchants brought for Occidental trade in “Indiennes” or printed and painted calicoes.

Whilst the earlier history of stamping patterns by hand on to textiles in the East has still to be written, a serious attempt has recently been made to account for the existence of this decorative process in Europe during several centuries prior to the introduction of the “Indiennes” above mentioned. As in the case of weaving and embroideries, specimens of printed stuffs have of recent years been obtained from disused cemeteries in Upper Egypt (Akhmim and elsewhere) and tell us of Egyptian use of such things. Some of them are now lodged in European museums. For indications that earlier Egyptians, Greeks and Romans were likely to have been acquainted with the process, one has to rely upon less certain evidence. Of textiles painted by Egyptians there are many actual examples. Apart from these there are wall paintings, e.g., those of Beni Hassan—about 2100 B.C.—in which are represented certain Asiatic people wearing costumes irregularly patterned with spots, stripes and zig-zags, which may have been more readily stamped than embroidered or woven. A rather more complicated and orderly pattern well suited to stamping occurs in a tomb about 1760 B.C. in which the female figure is painted. Herodotus, referring to the garments of inhabitants of the Caucasus, says that representations of various animals were dyed into them so as to be irreprovable by washing. Pliny describes “a very remarkable process employed in Egypt for the colouring of tissues. After pressing the material, which is white at first, they saturate it, not with colours, but with mordants that are calculated to absorb colour.” He does not explain how this saturation is done. But as it is clearly for the purpose of obtaining a decorative effect, stamping or brushing the mordants into the material seems to be intended. When this was finished the cloth was “plunged into a cauldron of boiling dye” and “removed the next moment fully coloured.” “It is a singular fact, too, that although the dye in the pan is of one uniform colour, the material when taken out of it is of various colours according to the nature of the mordants that have been respectively applied to it.” Egypto-Roman bits of printed stuffs from Akhmim exhibit the use, some three hundred years later than the time of Pliny, of boldly cut blocks for stamping figure-subjects and patterns on to textiles. Almost concurrent.

When Cortes conquered Mexico he sent to Charles V. cotton garments in black, green, red, yellow, blue and white. The North American Indians have a mode of applying patterns in different colours to cloth (see Parnell’s Dyeing and Calico Printing, p. 12).
with their discovery was that of a fragment of printed cotton at Arles in the grave of St Caesarius, who was bishop there about A.D. 542. Equal in archaeological value are similar fragments found in an ancient tomb at Quedlinburg. These, however, are of comparatively simple patterns. Other later specimens establish the fact that more important pattern-printing on textiles had become a developed industry in parts of Europe towards the end of the 12th and the beginning of the 13th century.

According to Forrer (Die Kunst des Zeugdrucks, 1898) medieval Rhenish monasteries were the cradles of the artistic craft of ornamental stamp or block cutting. In rare monastic MSS. earlier in date than the 13th century, initial letters (especially those that occurred frequently) were sometimes stamped from hand-cut blocks; and German deeds of the 15th century bear names of block cutters and textile stampers as those of witnesses. Between the 12th and 14th centuries there was apparently in Germany no such weaving of rich ornamental stuffs as that carried on in Spain and Italy, but her competitive and commercial instincts led her to adopt her art of stamping to the decoration of coarse textiles, and thus to produce rather rough imitations of patterns woven in the Saracenic, Byzantine and Italian silks and brocades. Amongst the more ancient relics of Rhenish printed textiles are some of thin silken stuff, impressed with rude and simplified versions of such patterns in gold and silver foil. Of these, and of a considerable number of later variously dyed stout linens with patterns printed in dark tones or in black, specimens were collected from various towns and old churches. From these several bits of evidence Dr Forrer propounds an opinion that the printing of patterns on textiles as carried on in several Rhenish towns preceded that of printing on paper. He proceeds to show that from after the 14th century increasing luxury and prosperity promoted a freer use of woven and embroidered stuffs, in consequence of which textile-printing fell into neglect, and it was not until three centuries later that it revived, very largely under the influence of trade importing into Europe quantities of Indian printed and painted calicoes.

Augsburg, famous in the 17th century for its printing on linens, &c., supplied Alsace and Switzerland with many crafts- men in this process. After the revocation of the edict of Nantes, French refugees took part in starting manufactories of both painted and printed cloths in Holland, England and Switzerland; some few of the refugees were allowed back into France to do the same in Normandy: manufactories were also set up in Paris, Marseilles, Nantes and Angers; but there was still greater activity at Geneva, Neuchâtel, Zürich, St Gall and Basel. The first textile-printing works in Great Britain are said to have been begun towards the end of the 17th century by a Frenchman on the banks of the Thames near Richmond, and soon afterwards a more considerable factory was established at Bromley Hall in Essex; many others were opened in Surrey early in the 18th century. At Mulhouse the enterprise of Koechlin, Schmatzer and Dollius in 1746, as well as that of Oberkampf at Jouy, led to a still wider spread of the industry in Alsace. In almost every place in Europe where it was taken up and followed, it was met by local and national prohibitions or trade protective regulations and acts, which, however, were gradually overcome.

Towards the end of the 18th century a revolution in the British manufacture of printed textiles was brought about through the invention of cylinder or roller printing from metal plates. This is usually credited to Oberkampf of Jouy, but it seems to have also occurred to a Scotsman named Bell, and was successfully applied in a large way about 1785 at Monsey near Preston. From this and the calico-printing works at Manchester in 1793, and in Scotland in 1768, the present huge proportions of the industry in the United Kingdom have grown.

Illustrations accompanying this brief account merely indicate a few types of patterns used in various European countries up to the beginning of the 19th century. Typical specimens of East Indian painted and printed calicoes for coverlets and other draperies are shown in the Indian division of the Victoria and Albert Museum. These are sui generis, and therefore differ from the bulk of Western prints on chintz, cretonne, &c., which together with a less quantity of printing on satin, silk, velvet, crêpe and the like are principally from adaptations of block-printing patterns. An interesting example of one of these patterns, chiefly of this character, was made by M. Corinmand between 1856 and 1860, and is preserved in the National Art Library at South Kensington. For many years of the latter part of the 19th century, William Morris designed and produced attractively ingenious floral and bird patterns, admirable in contrasts of bright colours, frequently basing his arrangement of crisply defined forms in them upon that of Persian surface ornament. His style, which, on its appearance struck a distinctive note, has very considerably affected numbers of British and foreign designers of printed patterns whether for textiles or wall papers.

The portion of linen hanging or valance given in fig. 1 (Plate I.) comes from an ancient cemetery at Khnûm in Upper Egypt. The linen dyed blue bears ornamentation with figures undyed or reserved, through the previous application to it, by means of a stamped block, of somewhat tachygraphy. The design, which the author attributes to Plisty. The design and cutting of the block were no doubt the work of Coptic artificers, the style of the composition being Egyptian-Roman of the 6th century A.D. On the child's tunic dyed blue (fig. 2) the simple trellis and floral pattern is similarly produced by the "reserve" process, and the specimen is of the same provenance as that of fig. 1. It is perhaps rather earlier in date. In the 4th century A.D. in Egypt, a fragment of red silk printed in red, green and black from wood-blocks, thus illustrating another method of applying colours to textiles. It is probably Rhenish work in the 12th or 13th century, and came from the church of Aten in Burundi. The ornament, however, is a survival of a scheme of pattern which was in use in Perso-Roman weavings as early as the 7th century A.D. Fig. 4 shows a piece of red silk printed with a Rhenish adaptation of a 13th-century North Italian weaving pattern possessing earlier Byzantine features. The design in fig. 5 is another Rhenish version of a richer style of 14th-century North Italian weaving. An advance in refinement of block-cutting is seen in fig. 6, a Rhenish adaptation of a 14th-century North Italian pattern often employed in brocade weaving of that period. The pattern in fig. 7 (Plate II.) is typical of a style introduced during the 15th century in sumptuous damask satins, and velvets woven at Florence, Genoa and Venice. Very different is the style exemplified in fig. 8, taken from a Dutch 17th-century "Indiënne," the trade name for such prints. The repeated wide and narrow stripes recall a scheme of which the 15th century employed for brocades; the intertwining floral ornament closely resembles such as occurs in 16th-century Indian painted and printed cottons. Fig. 9 is a 19th-century Italian design in the style of the Persian, the spreading tree device being used in Indian palmamores from the 16th century onwards to the present day. These, however, were either painted or printed from wood-blocks, whereas for this Indian copy engraved metal plates were used, after the manner of the process which was started, as already mentioned, by Oberkampf and Bell in the 18th century. The remaining figures 10, 11 and 12 are from stuffs metal-printed with subjects of a pictorial character which had a vogue for some time. In fig. 10—A French print—are family groups; shepherds and shepherdesses with their flocks; children at play; buildings, rocks, trees, &c.; the decorative effect of which, for the purposes of curtains and furniture covers, resulted mainly from the ordered repetition of these somewhat unrelated details. A landscape with a Chinese pagoda was repeated in lengths of the English cotton print, a piece of which was cut to fit the back of a chair, as in fig. 12. A linen panel was printed in colours with a stipple engraving to be used as a small fire screen. The style reflects the pseudo-classical taste of the end of the 18th century in England. Beneath the group of figures in the original is an inscription, "London, engraved and published, August 1, 1799, by M—Bost No. 207 Piccadilly." This sort of printing has practically disappeared: it was unsuitable for manufacture on a large scale.
