University of Arizona

There is some information which is necessary in order to perform automatic memory management:

- 1. We need to find the roots of the object graph, i.e. the pointers from the stack, registers, or global variables which point to objects on the heap.
- 2. We need to know the size, the beginning, and end of each object.
- 3. For each object we need to find which of its fields are pointers.
- Unfortunately, some languages have been designed so that it is impossible to determine this information.
- C and C++ are the two most popular such languages.

- C and C++ don't separate safe and unsafe features (such as address and bit manipulation) which are sometimes needed in systems programming.
- Modula-3 has similar unsafe features as C and C++ but they can be encapsulated into unsafe modules, which don't mess up the safety of the main (safe) part of the program.

Most GC algorithms assume that there is always a pointer to the beginning of every object. Depending on the code generator, that may or may not be true.

```
f(g,s) char (*g)(); char * s;

{ int i; int l = strlen(s);
  for (i = 0; i < l; i++)
    s[i] = (*g)(s[i]); }</pre>
```

There may be no pointer to s[0].

We need to know

- 1. the roots of the object graph.
- 2. the size, the beginning, and end of each object.
- 3. which object fields are pointers.

Finding Roots:

```
Foo* f = new foo; // f = 0x53f36

f = NULL; // f* is garbage

int i = 0x53f36; // points to f...
```

Finding the beginning:

Conservative Garbage Collection

Conservative GC

Works OK for uncooperative languages (C, C++) where we can't distinguish between pointers and integers. Sometimes fails to reclaim all garbage.

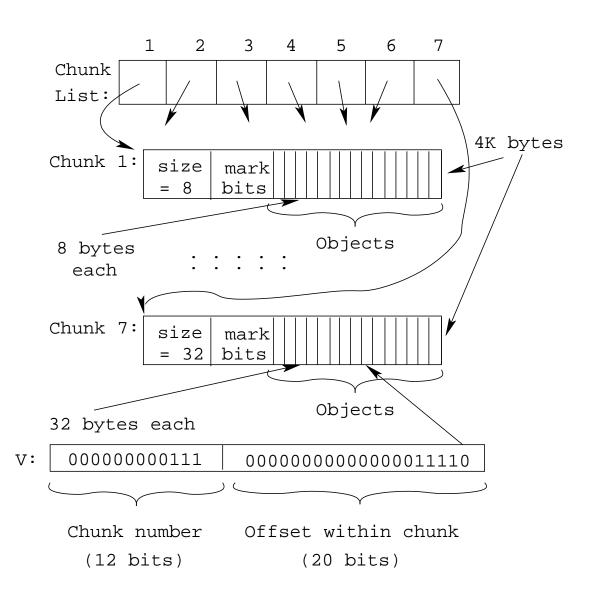

Main Ideas:

- Allocate memory in chunks. Each chunk holds a collection of objects of a certain size (i.e. it's easy to find the start of objects).
- Chunks are numbered. A pointer consists of 12 bits of chunk number (C) + 20 bits of offset within the chunk (O).

Conservative GC...

- To check whether a value V=(C,O) is a pointer to some object we check that
 - 1. Heap-bottom $\leq V \leq$ Heap-top,
 - 2. FirstChunk# < C < LastChunk#
 - 3. the offset *O* is a multiple of the object size in chunk *C*.

Conservative GC...
