Dynamic Memory Management

- The run-time system linked in with the generated code should contain routines for allocation/deallocation of dynamic memory.

Pascal, C, C++, Modula-2 **Explicit deallocation** of dynamic memory only. I.e. the programmer is required to keep track of all allocated memory and when it's safe to free it.

Eiffel **Implicit deallocation** only. Dynamic memory which is no longer used is recycled by the **garbage collector**.

Ada Implicit **or** explicit deallocation (implementation defined).

Modula-3 Implicit **and** explicit deallocation (programmer's choice).

Interface to Dynamic allocation

C, C++: `char* malloc(size)` and `free(char*)` are standard library routines.

Pascal: `new(pointer var)` and `dispose(pointer var)` are builtin standard procedures.

Java: `new(class name)` is a standard function.

LISP: `cons` creates new cells:

Explicit Deallocation

- Pascal's new/dispose, Modula-2's ALLOCATE/DEALLOCATE, C's malloc/free, C++'s new/delete, Ada's new/unchecked_deallocation (some implementations).
- **Problem 1:** Dangling references: `p=malloc(); q=p; free(p);`
- **Problem 2:** Memory leaks, Heap fragmentation.

Memory Leaks

```
DEFINITION MODULE Complex;  
  TYPE T;  
  PROCEDURE Create (Re, Im : REAL) : T;  
  PROCEDURE Add (A, B : T) : T;  
END Complex.
```

```
IMPLEMENTATION MODULE Complex;  
  TYPE T = POINTER TO RECORD  
    Re, Im : REAL; END;  
  PROCEDURE Create (Re, Im : REAL) : T;  
  BEGIN  
    NEW(x); x↑.Re := Re; x↑.Im := Im;  
    RETURN x; END Create;  
  PROCEDURE Add (A, B : T) : T;  
  BEGIN  
    NEW(x); x↑.Re := ...; x↑.Im := ...;  
    RETURN x; END Add;  
END Complex;
```

Memory Leaks...

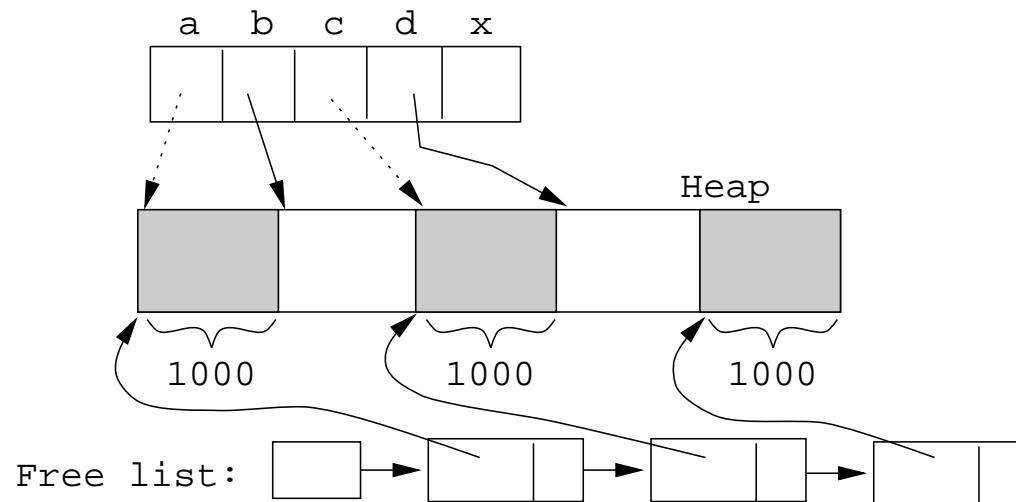

```
MODULE Use;  
  IMPORT Complex;  
  VAR a,b,c,d : Complex.T;  
BEGIN  
  a := Complex.Create(1.0, 2.4);  
  b := Complex.Create(3.4, 4.0);  
  c := Complex.Create(9.4, 6.6);  
  d := Complex.Add(a,Complex.Add(b,c));  
END Use.
```

Complex.Add(b, c) creates a new object which can never be reclaimed.

Fragmentation

```
VAR a, b, c, d : POINTER TO  
    ARRAY [1..1000] OF BYTE;  
VAR x : POINTER TO  
    ARRAY [1..2000] OF BYTE;  
  
BEGIN  
    NEW(a); NEW(b); NEW(c); NEW(d);  
    DISPOSE(a); DISPOSE(c); NEW(x);
```

- Without compaction the last allocation will fail, even though enough memory is available.

Implicit Deallocation

- LISP, Prolog – Equal-sized cells; No changes to old cells.
- Eiffel, Modula-3 – Different-sized cells; Frequent changes to old cells.
- When do we GC?

Stop-and-copy Perform a GC whenever we run out of heap space (Modula-3).

Real-time/Incremental Perform a partial GC for each pointer assignment or `new` (Eiffel, Modula-3).

Concurrent Run the GC in a separate process.

Implicit Deallocation...

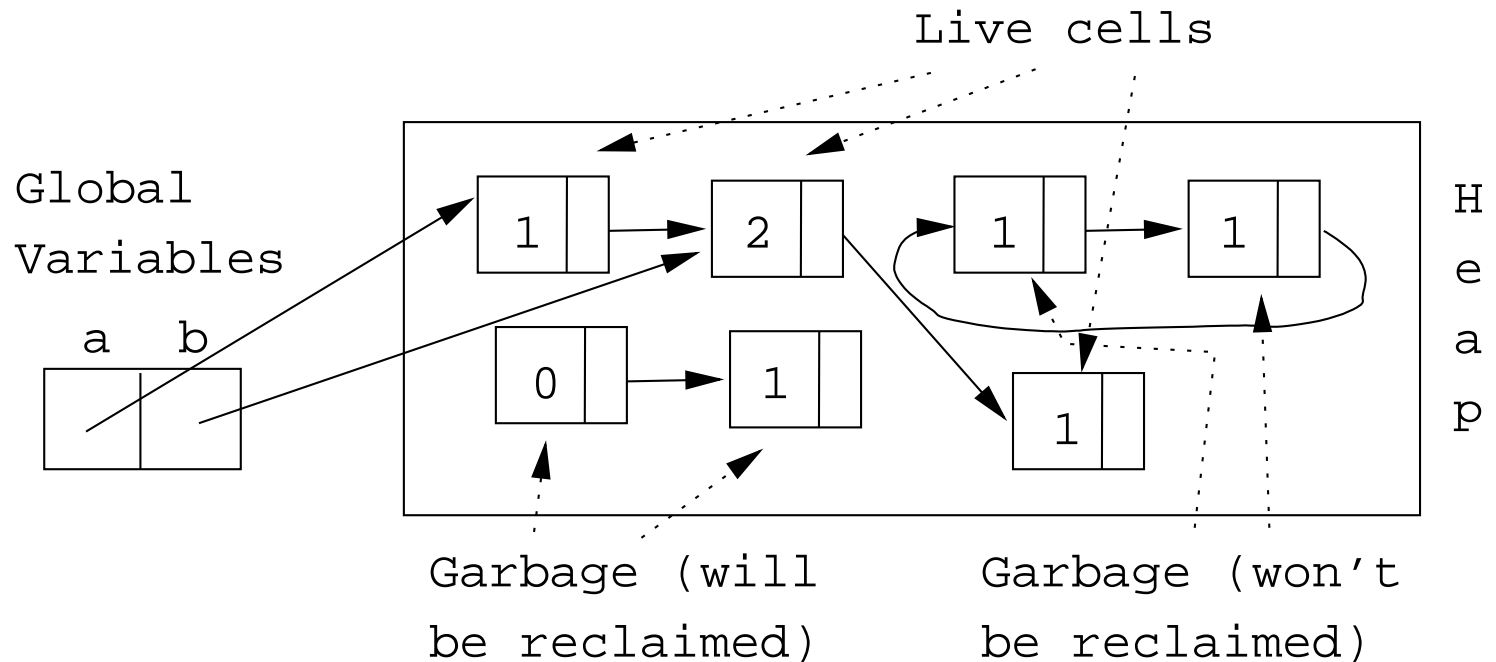

- Fragmentation – Compact the heap as a part of the GC, or only when the GC fails to return a large enough block.
- Algorithms: Reference counts, Mark/ssweep, Copying, Generational.

Algorithm: Reference Counts

- An extra field is kept in each object containing a count of the number of pointers which point to the object.
- Each time a pointer is made to point to an object, that object's count has to be incremented.
- Similarly, every time a pointer no longer points to an object, that object's count has to be decremented.
- When we run out of dynamic memory we scan through the heap and put objects with a zero reference count back on the free-list.
- Maintaining the reference count is costly. Also, circular structures (circular linked lists, for example) will not be collected.

Algorithm: Reference Counts...

- Every object records the number of pointers pointing to it.
- When a pointer changes, the corresponding object's reference count has to be updated.
- GC: reclaim objects with a zero count. Circular structures will not be reclaimed.

Algorithm: Reference Counts...

NEW(p) is implemented as:

```
malloc(p); p↑.rc := 0;
```

p↑.next := q is implemented as:

```
z := p↑.next;  
if z ≠ nil then  
    z↑.rc--; if z↑.rc = 0 then reclaim z↑ endif  
endif;  
p↑.next := q;  
q↑.rc++;
```

- This code sequence has to be inserted by the compiler for *every* pointer assignment in the program. This is very expensive.
