Code Generation
with BEG

BEG and Cocktail I

- We'll talk about a code generator generating system called `BEG`.
- `BEG` is part of a larger compiler construction toolset called `Cocktail`. `Cocktail` has tools that construct parsers, scanners, semantic analysers, intermediate code generators and machine code generators.
- Most of the `Cocktail` tools are now commercial products, but there are still some free early versions around on the net.
- `BEG` is a program which takes as input a specification consisting of **code generation** rules, a description of the target architecture, and a description of the intermediate representation.

BEG and Cocktail II

- Based on the machine description `BEG` produces a code generator which operates by pattern-matching on the intermediate representation.
- One can choose between several (at least two...) types of register allocators.
- The code generator constructed by `BEG` takes as its input a sequence of expression trees. Output can be just about anything; we will produce textual assembly code.
- The code generator takes care of (almost) all aspects of code generation: instruction selection, register allocation, register assignment, and register spilling.
- The next slide shows the overall structure of a compiler built by `Cocktail`.

The Phases of Beg I

- The code generator generated by BEG runs in three phases.
- The first phase uses pattern matching to construct a **minimal cover** of the input tree: the code generator will find the set of code generator rules which will produce the cheapest (fastest) code sequences. BEG does this by **covering** the input tree with the cheapest sequence of patterns.
- The second phase allocates register.
- The third phase generates the actual code.
- Another way of thinking about a minimal cover is to say that the selected patterns **reduce** the input tree to the **empty tree** by deleting matched parts of the input tree.

Intermediate Code

- When we build the code generator with BEG, BEG generates a module `Sparc.md/mi` which is the interface to the code generator.
- At compile-time we call procedures in this module to build the intermediate code tree.
- The code generator generated by BEG assumes that the intermediate code is in a tree format. The structure of the tree-nodes is described by a specification.

The Code Generator Specification

```
CODE_GENERATOR_DESCRIPTION Sparc;
INTERMEDIATE_CODE
    GlobalVar (id) -> IntExp;
    Plus IntExp + IntExp -> IntExp;

REGISTERS ....
RULES ....
END CODE_GENERATOR_DESCRIPTION Sparc.
```

Sparc.cgd

BEG

Interface to the
Code Generator

```
DEFINITION MODULE Sparc;
  TYPE IntExp;

  PROCEDURE GlobalVar (
    id : Identifier;
    VAR result : IntExp);

  PROCEDURE Plus (
    op1, op2 : IntExp;
    VAR result : IntExp);
 END Sparc;
```
Sparc.md

The Code
Generator

Instruction
Selector

Register
Allocator

Intermediate Code II

```
Integer   (value:  INTEGER) -> IntExp;
GlobalVar (id:  Identifier) -> IntExp;
Load      IntExp           -> IntExp;
Store     IntExp * IntExp;
Plus      IntExp + IntExp  -> IntExp;
```

- The $+$ ($*$)-sign makes the operator (non-)commutative (Plus is commutative since $a + b \equiv b + a$).
- Parentheses indicate input attributes, data passed from the front end to the code generator.
Cover Trees I

There are several alternative ways of thinking about the actions taken by BEG during code generation:

1. Find a set of patterns that covers the input tree, such that the total cost is minimized.

2. Build a tree (identical to the input tree) out of the available patterns, such that the total cost of the new tree is minimized.

3. Apply the patterns to the input tree, replacing the matched part of the tree with the right hand side of the pattern, until the tree is consumed. Chose the set of patterns with minimal cost.
Patterns:

Rule 1: + → reg

load, reg

+ (Cost=2)

sp, 4

```
ld [sp+4],Reg1
add Reg1,Reg2,Reg3
```

Rule 2 (Cost=1): 1 → reg

```
set 1,Reg1
```

Rule 3: :=

+, reg

sp, 4 (Cost=2)

```
st Reg1,[sp+4]
```

Definition 1:

:=

+, +

sp, 4, load, 1

+

sp, 4

⟹

:= Rule 3

+, + Rule 1

sp, 4, load, 1 Rule 2

+

sp, 4

Definition 2:

Rule 3: :=

+, reg

sp, 4

+

Rule 1: +

load, reg

+

sp, 4

+

Rule 2: 1

=

:=

+, +

sp, 4, load, 1

+

sp, 4

Definition 3:

:=

+, +

sp, 4, load, 1

+

sp, 4

Rule 2 ⟹

:=

+, +

sp, 4, load, reg

+

sp, 4

Rule 1 ⟹

:=

+, reg

sp, 4

Rule 3 ⟹

Rule 1:

Plus → Reg (c)
a: Reg, b: Reg

add a,b,c

```
RULE Plus Reg.a Reg.b -> Reg.c
COST 1;
EMIT{Write("add" a "," b "," c);};
```

Rule 2:

Load → Reg (r)
a: Address

ld [a], r

```
RULE Load Address.a -> Reg.r
COST 1;
EMIT{Write("ld" "[" a "]" "," r);};
```

Rule 3:

Store
a: Address, r: Reg

st r,[a]

```
RULE Store Address.a Reg.r
COST 1;
EMIT{Write("st" r, "[" a "]" );};
```

Rule 4:

GlobalVar id → Reg (r)
a

set a.id, r

```
RULE GlobalVar.a -> Reg.r
COST 2;
EMIT{Write("set" a.id "," r);};
```

Rule 5:

Integer value → Reg (r)
a

set a.value, r

```
RULE Integer.a -> Reg.r
COST 2;
EMIT{Write("set" a.value "," r);};
```

(Chain-)Rule 6:

Reg (r) → Address (a)

```
RULE Reg.r -> Address.a   COST 0;
EVAL{a.val:=0;}  EMIT{a.reg:=r;};
```

- These simple rules all contain three parts: a **pattern**, a **cost**, and an *emit*-part. The **pattern**-part describes a sub-tree which the rule matches, the **emit**-part describes the instructions to be generated by the rule, and the **cost**-part describes the cost of executing these instructions.

———————————— Explanations: ————————————

Rule 1, for example, states that on the SPARC there is an add-instruction which adds two registers into a third, and which executes in one (1) machine cycle.

Rule 2 says that we can load the value at a given address into a register using the `ld`-instruction. `Address` is a SPARC addressing mode which has several different forms.

Rule 5 shows how we can load an integer value into a register using the `set` pseudo-operation.

Rule 6 is known as a chain-rule. It generates no code but simply states how we may transform a value from one form to another. In this case the rule states how we can transform a register into the addressing mode `Address`. The Modula-2-code in the **EVAL**-part is executed during the code generator's cover phase, whereas the code in the **EMIT**-part is executed during the output phase.
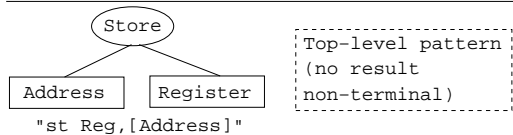

Beg Tree Patterns II

- A Beg pattern is normally a sub-tree where the leaves are non-terminals.
- A non-terminal represents a *storage class* on the machine, i.e. a register or some other addressing mode.
- Most patterns have a *result non-terminal*, which describes the type of storage class in which the instruction returns its result.
- Top-level patterns are distinguished by the fact that they do not have a result non-terminal. They therefore only match the root of an input expression tree.
- A chain rule transforms a value from one storage class to another. Often this can be done without generating any code. For example, if one instruction returns its result in a register, and the next instruction requires its argument in an address (e.g. a Sparc addressing mode which is either a register, the sum of two registers, or the sum of a register and a small offset), then we can use a chain rule that maps a register non-terminal to an address (without producing any code) rather than introducing an explicit rule for each instruction of that kind.

- We can use the same technique to handle machines with more than one register class (Address and Data Registers for the MC68XXX architecture, for example).
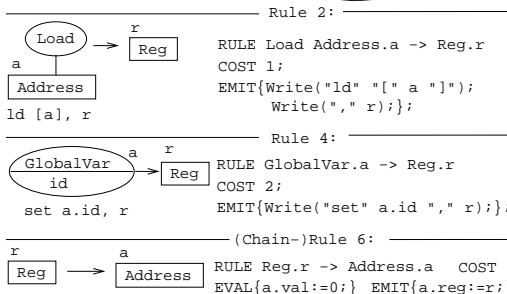

BEG Example I (d)

```
set A, %l0
ld  [%l0], %l0
set 314, %l1
add %l0, %l1, %l0
set A, %l1
st  %l0, [%l1]
```

Definition3 (Consume the tree):

Load → GlobalVar id = "A" ⟹ Rule 4 Load → Reg ⟹ Rule 6 Load → Address ⟹ Rule 2 Reg

Definition 1 (Cover the tree):

Load → GlobalVar id = "A" ⟹ Rule 2 Load / Rule 6 / GlobalVar id = "A" Rule 4

─────────── Rule 2: ───────────

Load → Reg r
a
Address

ld [a], r

```
RULE Load Address.a -> Reg.r
COST 1;
EMIT{Write("ld" "[" a "]");
     Write("," r);};
```

─────────── Rule 4: ───────────

GlobalVar id → Reg r
a

set a.id, r

```
RULE GlobalVar.a -> Reg.r
COST 2;
EMIT{Write("set" a.id "," r);};
```

─────────── (Chain-)Rule 6: ───────────

Reg r → Address a

```
RULE Reg.r -> Address.a   COST 0;
EVAL{a.val:=0;}  EMIT{a.reg:=r;};
```

Definition 3 (Consume the tree):

Rule 5 ⟹   Rule 1 ⟹

set a.value, r   add a,b,c

Definition 1 (Cover the tree):

Rule 1

Rule 5

```
───────────────── Rule 1: ─────────────────
```

add a,b,c

```
RULE Plus Reg.a Reg.b -> Reg.c
COST 1;
EMIT{Write("add" a "," b);
      Write("," c);};
```

```
───────────────── Rule 5: ─────────────────
```

set a.value, r

```
RULE Integer.a -> Reg.r
COST 2;
EMIT{Write("set" a.value);
      Write("," r);};
```

- A working `BEG` specification can be extended with new rules that produce better code in special cases.

Rule 6   Store   Rule 3

Rule 4   GlobalVar
          id = "A"   Plus   Rule 7

Rule 2   Reg   Integer
                 value=314

────────────── Rule 3: ──────────────

Store

a   r
Address Reg

st r,[a]

RULE Store Address.a Reg.r
COST 1;
EMIT{Write("st" r, "[" a "]");};

────────────── Rule 7: ──────────────

Plus ──→ Reg
              c
a   r
Reg   Integer
         value

add a,v,c

RULE Plus Reg.a Integer.v->Reg.c
CONDITION{(v.value>=-4195) &
          (v.value<=4195)};
COST 1;
EMIT{Write("add" a "," v.value
          "," c);};
Without Rule 7:

```
set A, %l0
ld  [%l0], %l0
set 314, %l1
add %l0, %l1, %l0
set A, %l1
st  %l0, [%l1]
```

With Rule 7:

```
set A, %l0
ld  [%l0], %l0
add %l0, 314, %l0
set A, %l1
st  %l0, [%l1]
```

Structure of
BEG Specifications

Structure of Sparc.cgd

- The main BEG specification for the SPARC architecture is stored in a file Sparc.cgd. It has the following global structure:

CODE_GENERATOR_DESCRIPTION Sparc;
INTERMEDIATE_REPRESENTATION
NONTERMINALS IntExp;
OPERATORS
  Intermediate code format
REGISTERS
  Description of registers
AVAIL (*Available registers*);
NONTERMINALS
  Description of addressing modes
Code generation rules
INSERTS
  Code to be inserted in generated modules
END CODE_GENERATOR_DESCRIPTION ⋯.

Intermediate Format

- This is how the tree-nodes are described:

CODE_GENERATOR_DESCRIPTION Sparc;
INTERMEDIATE_REPRESENTATION;
NONTERMINALS IntExp;

OPERATORS

```
Integer   ( value : INTEGER )->   IntExp;
GlobalVar ( id : Identifier )     ->   IntExp;
Load      IntExp                 ->   IntExp;
Store     IntExp  * IntExp;
Plus      IntExp  + IntExp  ->   IntExp;
```

...

END CODE_GENERATOR_DESCRIPTION ····.

SPARC Architecture

- We need to know the addressing modes the machine has and which registers are available.

1. **Integer Register**
   - global (%g0, %g1,..., %g7)
   - local (%l0, %l1,..., %l7)
   - input (%i0, %i1,..., %i7)
   - output (%o0, %o1,..., %o7)

2. **Floating Point Register**
   - (%f0, %f1,..., %f31)

3. **Address**
   - $reg_1 + reg_2$
   - $reg_1 + const_{13}$
   - $const_{13}$

4. **Register or Immediate**
   - reg_1
   - $const_{13}$

Registers and Addr. Modes

CODE_GENERATOR_DESCRIPTION Sparc;

        (val : INTEGER)
      (reg : Register);

  IntConst13 **COND_ATTRIBUTES**
      (val : INTEGER);
END CODE_GENERATOR_DESCRIPTION

BEG Rules

RULE Pattern consisting of register classes, addressing modes, operators, etc.

CONDITION Condition evaluated during cover phase. If result is FALSE rule will not be used.

COST Cost (in number of cycles) of using rule.

CHANGE Registers affected by generated code.

EVAL Code to evaluate attributes, build addressing modes, etc.

EMIT Code to generate target code.

RULE arg_1 arg_2 ... arg_n
-> result

CONDITION { *Boolean Modula-2-expression* };

COST *Integer*,

CHANGE (*Affected registers*);

EVAL { *Cover phase Modula-2-code* };

EMIT { *Output phase Modula-2-code* };

Advanced BEG Rules I

```
RULE Mult Reg.a(o0) Reg.b(o1)->Reg.c(o0)
COST 4;
EMIT {Write("mul...");}
```

- The mul instruction requires its arguments to be in registers %o0 and %o1, and returns its result in register %o0.

```
RULE Instr Reg.a(o0..06) -> Reg.b(o0)
COST 4;
EMIT {Write("...");}
```

- In order to use this rule, Beg has to make sure that the argument is in one of the specified registers.

Advanced BEG Rules II

```
RULE Call.c Arg;
COST 2;
CHANGE (g1..g6);
EMIT {Write("call...");}
```

- A procedure call affects all global registers.

Computed Registers:

```
RULE Instr Reg.a -> Reg.c({Mod-2 Expr})
COST 4;
EMIT {Write("...");}
```

- The expression returns a suitable register. This is useful when passing parameters in registers.

Advanced BEG Rules III

_____ Constant Folding: _____

- The Modula-2 code in in the **EVAL** part of a rule is executed
  during the cover phase. It can therefore be used to evaluate
  (fold) constant expressions.
- For example, an expression $a + 2 * 3$ would be translated into
  code for $a + 6$, with $2 * 3$ evaluated at compile time.
_____ Rule 9: _____

```
RULE Plus Integer.a Integer.b
        -> Integer.c
COST 0;
EVAL {c.value := a.value + b.value}
```

_____ Complex Patterns: _____

- A BEG rule can be given an arbitrarily complex pattern. The pattern part of a rule is actually a **preorder** traversal of a tree pattern.
- The following example shows how we can specify a multiply-and-add instruction:

_____ Rule 10: _____

```
RULE Plus Reg.a Mult Reg.b Reg.c -> Reg.d
COST 2;
EMIT {write("MADD ...");}
```

Inserting Modula-2 Code I

- The last part of a `BEG` specification consists of instructions that inserts extra code into the generated modules.
- Often this code consists of **IMPORT** statements that makes it possible for the generated modules to find types and procedures defined by us.
- For every module `M` generated by `BEG`, you can insert code into its definition and implementation modules. This is done in so called **insertion points** (`Ip`):

```
IpM_d { Code inserted into M.def,
        after IMPORT statements. }
IpM_i { Code inserted into M.mod }
```

- There are special insertion points called `IpInOut` (for inserting IO routines) and `IpNoReg` (for inserting code to call when register allocation fails).

```
CODE_GENERATOR_DESCRIPTION Sparc;
INSERTS
   IpInOut {
   FROM AsmFile IMPORT
      Create,...,FatalError;
   }
   IpIR_d {
      FROM GcgBase IMPORT
               Identifier, Condition;
   }
   IpIR_i {
      FROM GcgBase IMPORT Identifier, ...,
   PrintCondition;
   }
   IpNoReg {
      FatalError ("Reg alloc failed.");
      HALT;
   }
```

Example: IBM370

```
CODE_GENERATOR_DESCRIPTION  IBM370;
INTERMEDIATE_REPRESENTATION
NONTERMINALS Value;
OPERATORS

```

Summary

- Read the Tiger Book, Chapter 9, *Instruction Selection*.
- Read "Emmelmann, Schröer, Landwehr: *BEG – A generator for Efficient Back Ends*", PLDI '89.
- Or, read the Dragon Book, pp. 572–580.

Summary

- In the `Sparc` example, the `val`-attributes in the `Address`, `RegOrImm`, and `IntConst13` addressing modes are specified as **condition attributes**. This means that this attribute gets its value during the code generator's *cover phase*. The register attributes, on the other hand, get their values during the *output phase*.
